

M D T S

**TRANSACTION WITH
CREDIT AUTHORIZATION SYSTEM**

MDTS COLLECTIVE STORE AND FORWARD SYSTEM
WITH DISC CREDIT AUTHORIZATION
AND CHRONOLOGICAL TRANSMISSION

Release Date: December 1, 1971

CR 0602

This manual documents the software package used in the Modular Data Transaction System (MDTS) environment at Sears. It does not include documentation on RBSA programs or utilities used by Sears.

All revisions prior to December 1, 1971, have been incorporated into this manual. The revision dates can be found at the bottom of each page.

All documentation of this MDTS software package prior to December 1, 1971, is superceded by this manual.

This release contains the following enhancements:

1. Improvement of criteria testing for ENDAY.
2. Addition of ATT12 message for logical day changing.
3. SCA partition buffer sharing for transmitting and receiving data.
4. Receipt of any communications option other than Function Text Option 2, Option 000, or Option 0nn will cause a buffer reset in the SCA partition similar to Function Text Option 1.
5. The printing of the Singer-Friden Company title, MDTS System software module name, second Julian form release date on the console device during program loading.
6. Correction of all outstanding software problems reported prior to this date.

This software release is compatible with all previously released MDTS System support and utility programs as well as all external referencing programs with the exception of the RBSA Series program NFR200 which is being concurrently released with the MDTS System software.

INTRODUCTION

SECTION 1

INTRODUCTION

The MDTs Collective Store and Forward System with Disc Credit Authorization operates with a minimum 10K common, 2K partition zero, 3K SCA partition, and 1K for each terminal partition.

Partition zero monitors all activities, accepts commands for reporting or altering data flow, automatically reports status at various points and reports machine malfunctions, should they occur.

The SCA partition handles all communication between the System Ten and a host computer. It requires two channels, but is considered one partition.

The terminal partitions service the point-of-sale terminals by responding to a credit inquiry, accepting transactions, and writing the completed transactions on disc. They also retrieve transactions during a host poll and update the credit file during a host select.

All partitions have access to the common data areas and routines. Software flags prevent simultaneous use of given common routines by more than one partition.

When the program is in normal operation, point-of-sale terminals will have first priority for service. A credit inquiry will be answered immediately. A transaction will be logged in a core queue. If no terminal attached to a particular partition is requesting service, the system will allow that partition to write data from the queue to disc. If the queue is empty, the system will allow a host computer request to be serviced.

At the completion of any single task, or upon recognizing no tasks pending, the partition in charge releases the system to the next partition. If the next partition is a terminal partition, the process is repeated. If it is the SCA partition, the system will check for a host command if none is currently pending, or will resume execution at the point it released control if a command is being processed.

When control passes to partition zero, a pending service request is acknowledged and serviced. If no service request is pending, any message passed to partition zero from one of the other partitions will be printed. If there is no message, control passes to partition one.

MULTI-PARTITION LOADING

SECTION 2

MULTI-PARTITION SYSTEM LOADING

System loading in a multi-partition environment is accomplished with a special CHannel LOad and Execute program CHLOE. Features of this program are:

1. Checking of common size to insure that the size requested is available.
2. Computation of the number of blocks of core, 100 positions long, between the figure provided in CHLOE card 0002 and the upper limit of common less six blocks. This figure is placed in core positions 300-301 of common.
3. Computation of a figure, 200 core positions below common maximum and placement of that figure in core positions 302-303-304-305 of common.
4. Placing the number of a partition in core position 45, 46, 47 and 48 of the partition.
5. Placing five times the number of a partition in core position 25, 26, 27 and 28 of the partition.
6. Placing three times the number of a partition in core position 35, 36, 37 and 38 of the partition.
7. The ability to load any program into any partition or the same program into all partitions.
8. The ability to automatically cycle any partition that is not loaded.
9. The ability to request loading into non-existent partitions.
10. Automatic execution of programs commencing with partition zero upon completion of loading.

Restrictions of this program are:

1. Operates in an environment which includes at least one partition besides partition zero.
2. The first existing partition after partition zero cannot be an MTIOC type. (It must execute a recovery instruction at position zero when forced into a LOAD state instead of issuing a read control). Other partition following the first existing partition can be any type.
3. Partition zero will start at position 0300 unless the ST6 card is modified. All other partitions must begin at position 0000.
4. The common program to be loaded cannot insert any data or coding below position 320. These 20 positions are available for labeled work areas.

5. The partition zero program, to be loaded, cannot insert any data or coding below position 300.

The system to be loaded into the multi-partition environment is first assembled and the output intermixed with CHLOE. Only the output cards designated T are used and all other types from the assembly are to be discarded including the S type card(s).

CHLOE text cards 0001 and 0002 may require modification for various system configurations.

CHLOE card number 0001 designates, in columns 8 and 9, the amount of common core required for proper program operation. Comparison is made of this figure to the actual amount of common area available and an error message is written if the common area is not sufficient.

CHLOE card number 0002 designates in columns 8 and 9, the first two digits of the queue starting address plus 6. This is utilized in determining the block count of the queue and reserves three blocks in both front and rear for overflow purposes. The queue must start on an even hundred integer as the number of blocks is established from the first two digits. The queue maximum pointer, INPXA, is also established at 200 core positions below the common maximum.

If using the MDTs Basic CHLOE Loader, CHLOE1, text cards 0001 and 0002 will be immediately preceded by the ST1, ST2 and ST3 cards. These three cards comprise a re-entrant bootstrap for loading CHLOE and portions of the user program from any IOC device (card reader, 7102 paper tape reader, etc.). These cards must be present when using either the MDTs Bootstrap to Disc or Bootstrap to Magnetic Tape. They are replaced by the ST0 card when using DNF CHLOE, CHLOE3.

CHLOE card number ST4 designates which partition or partitions are to be loaded with the assembly output which would immediately follow. Columns 40 through 59 indicate partitions 00 through 19 and a flag (1) in the partition position will load that partition.

A separate program may be loaded into another partition by inserting another ST4 card immediately prior to the new program. Partitions do not have to be loaded with program but may not have more than one program assigned. Partitions which are not loaded with program will be given an automatic cycling instruction so that they will not interfere with other partitions. Any attempt to load more than one program into the same partition will print an error message and terminate the loading program.

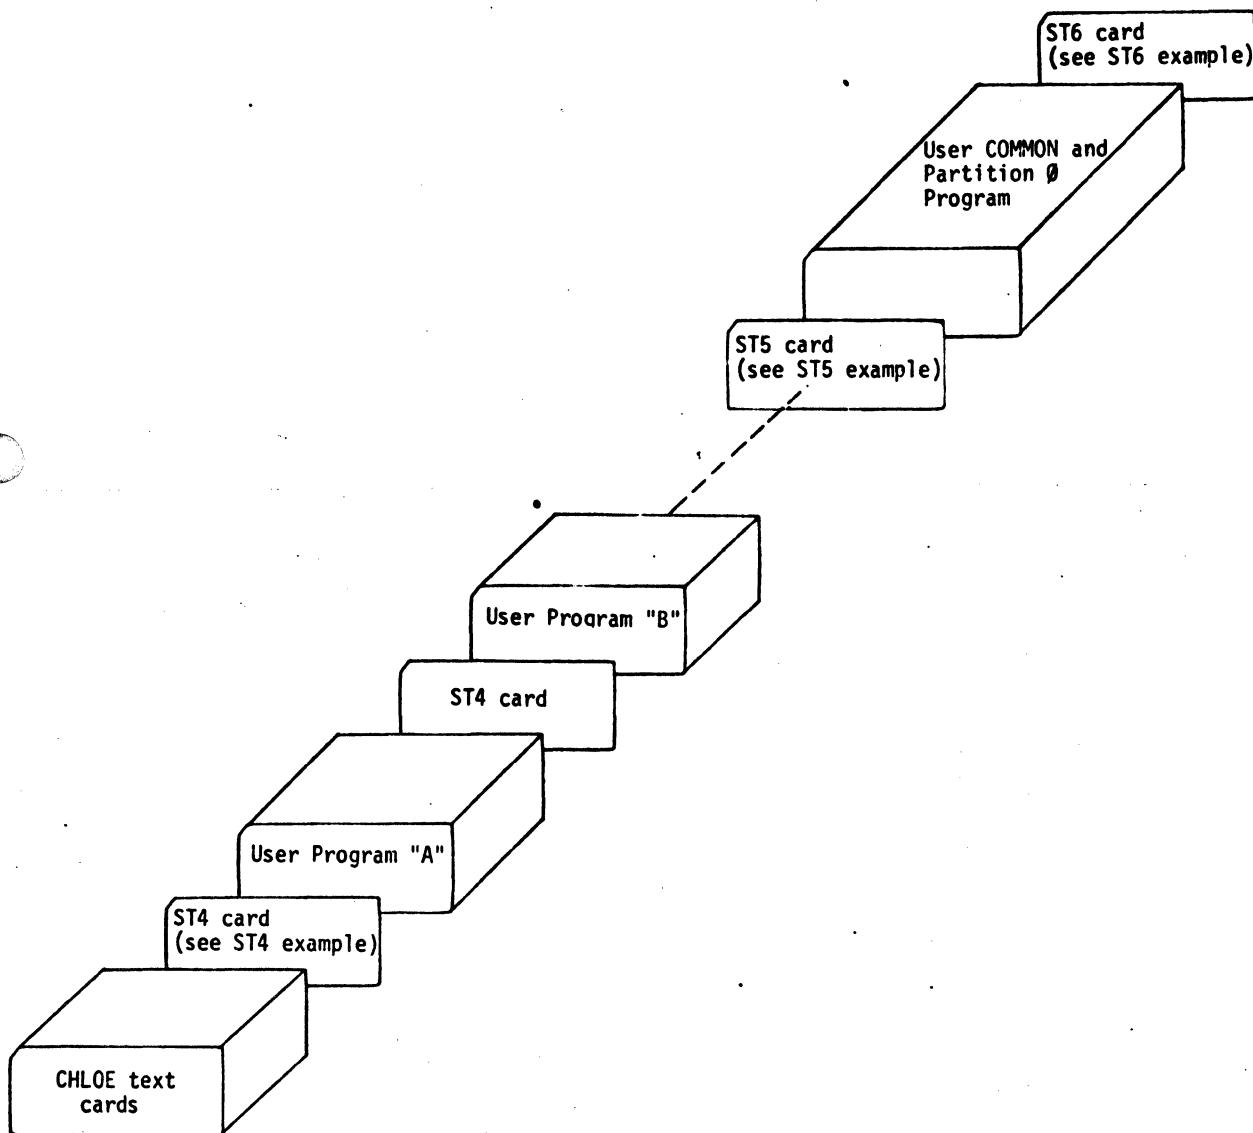

CHLOE card number ST5 indicates that partitions 1 through 19 have been loaded, if they were requested, and that the data for partition 0 and/or the common area follows.

CHLOE card number ST6 is the last card of the sequence and terminates the multi-partition loading process.

The following illustrations and supporting examples describe the deck contents for systems programs to be loaded with CHLOE from any media. Normally the system program deck is separated into its various partition programs and the appropriate CHLOE program and CHLOE control cards inserted as required. The card deck thus arranged can be converted to paper tape at this point if necessary. The section following the illustrations describes how the system program is loaded.

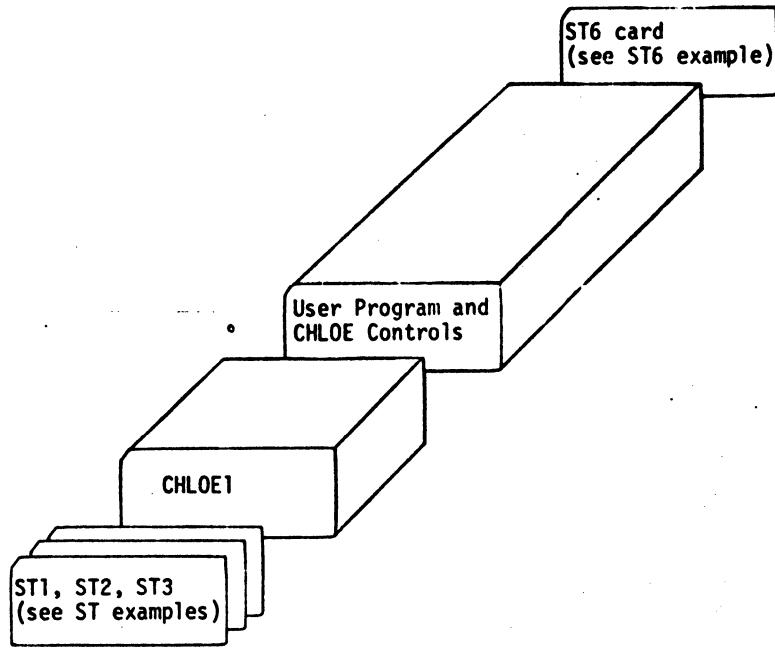

BASIC CHLOE LOADER

CARD DECK FORMAT

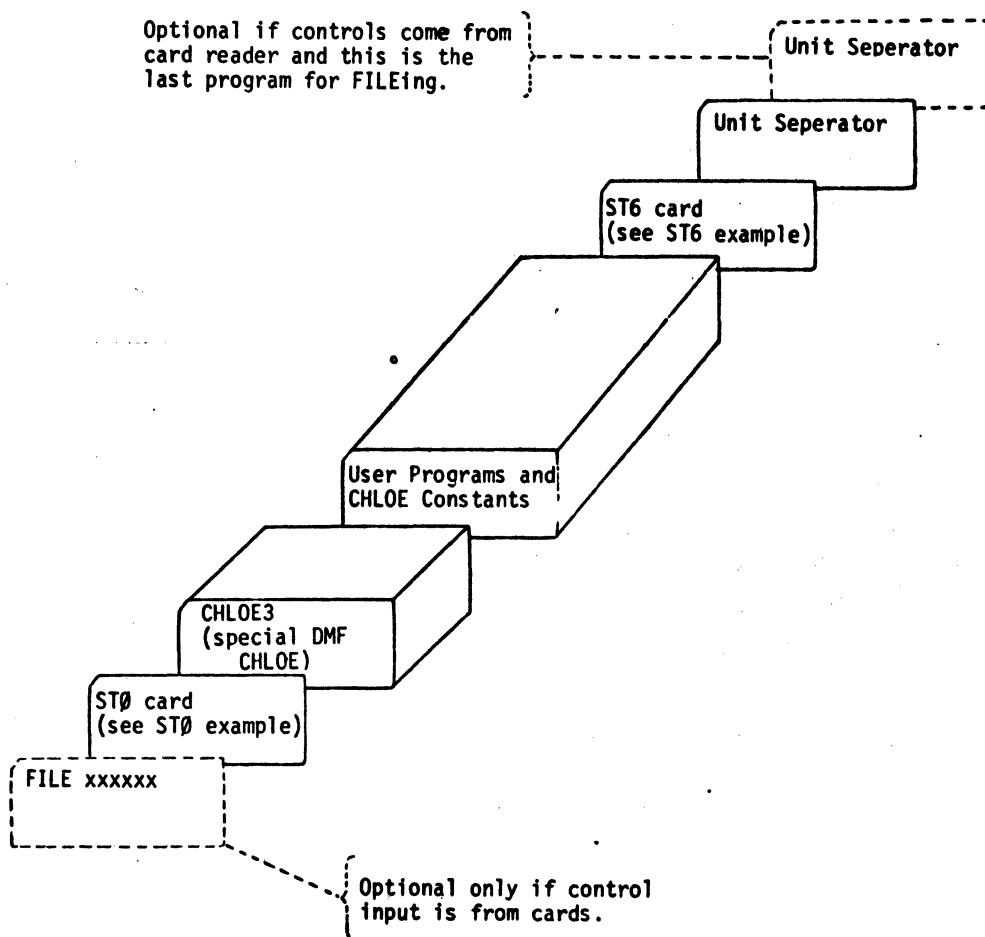

CHLOE1

MDTS BASIC CHLOE

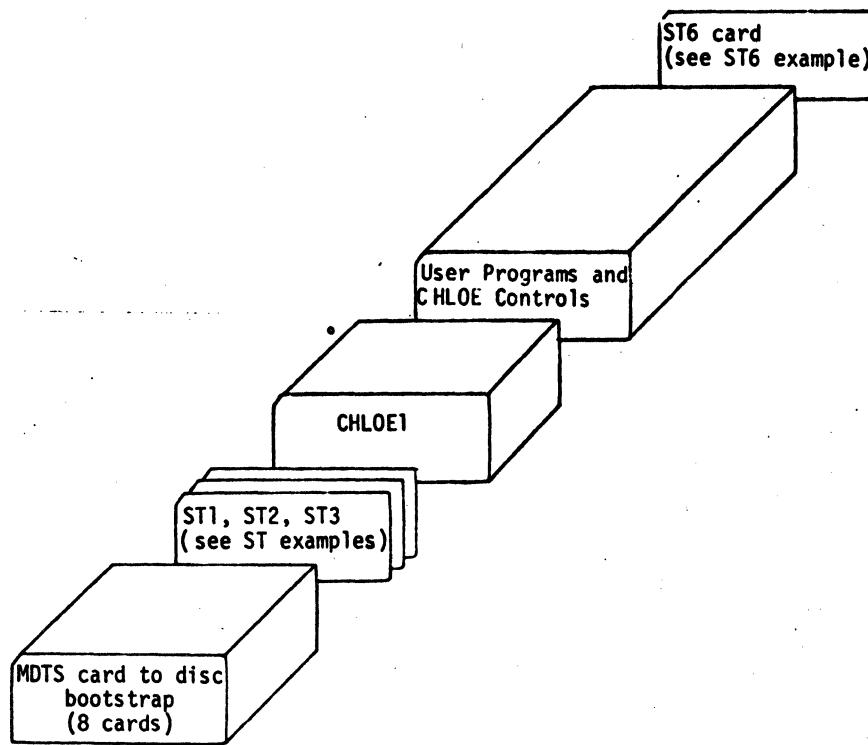

CHLOE3

DMF CHLOE LOADER

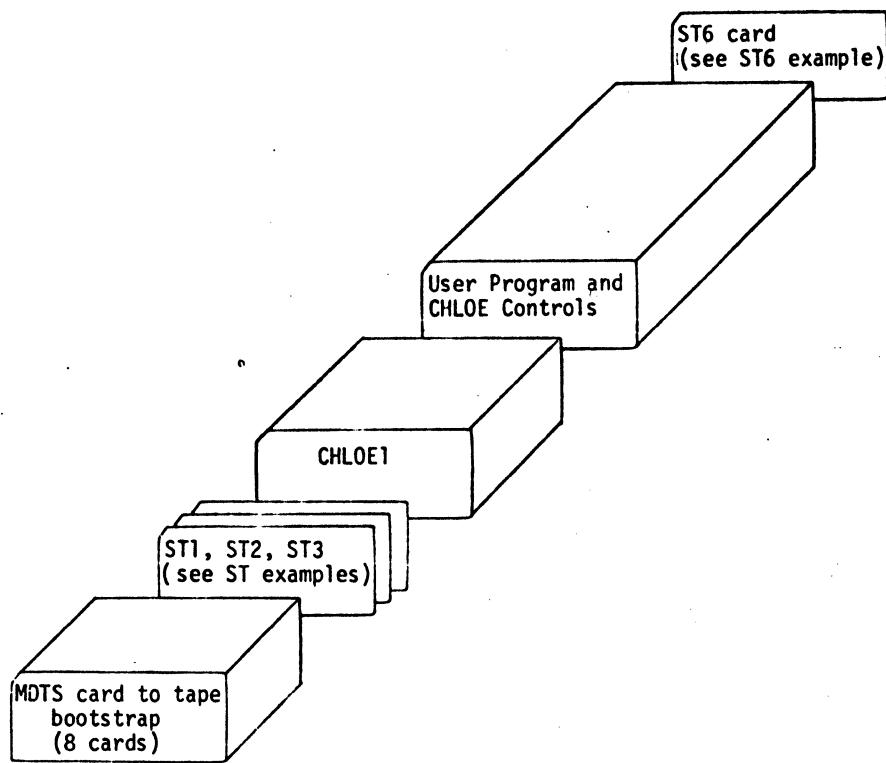

NOTE: Follow DMF FILE procedures for the system.

CHLOE5
MDTS BOOTSTRAP TO DISC

STØ CARD EXAMPLE

Card Columns

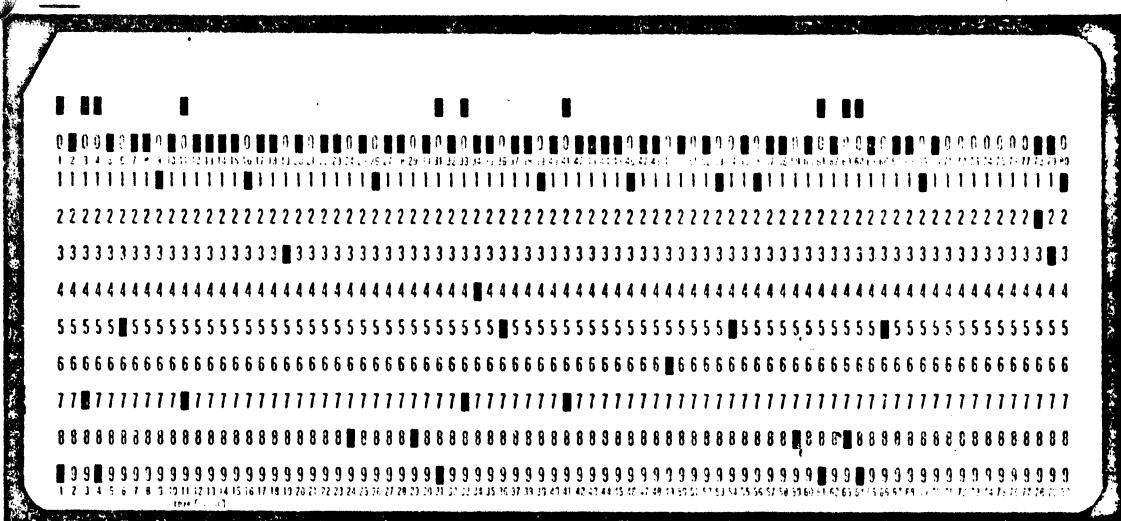

- | | |
|-------|--|
| 1-5 | S card format and address used to execute the Inhibit Switch mode instruction and branch in this card. |
| 6-10 | Not Used |
| 11-25 | Inhibit Switch Instruction and Branch to Loader. |
| 26-30 | Not Used |
| 31-77 | Comments |
| 78-80 | STØ |

Contents

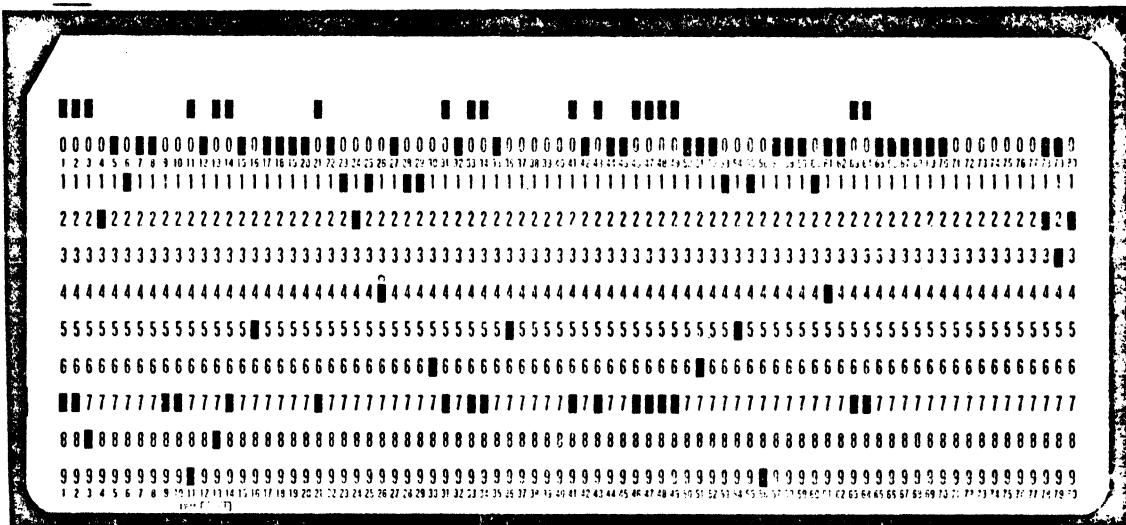

ST1, ST2, ST3 CARD EXAMPLES

These cards are the loader cards which will load the CHLOE loader. They are generated separately from CHLOE and added to the CHLOE deck prior to distribution.

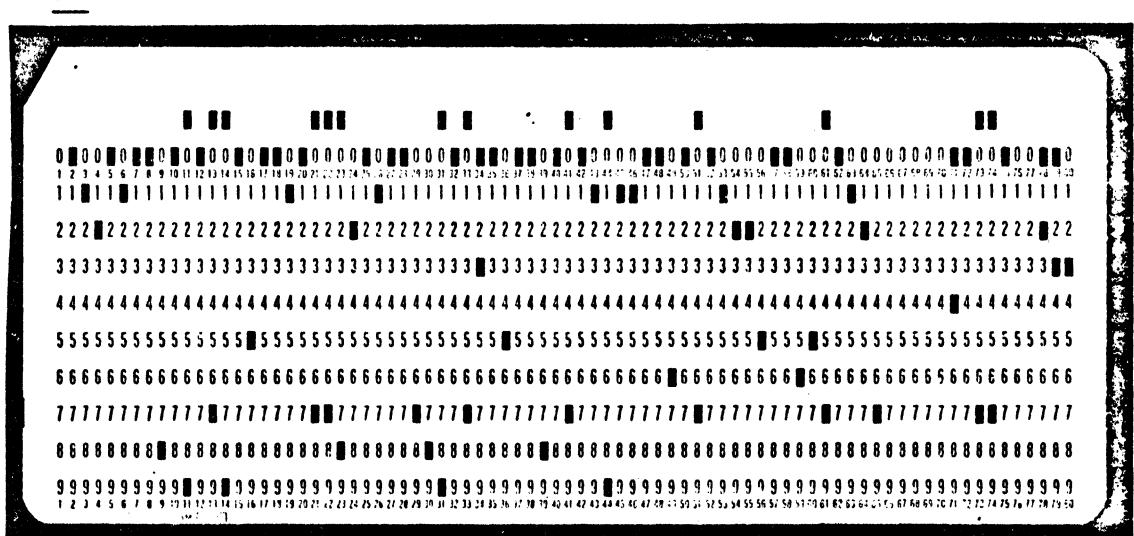

ST1

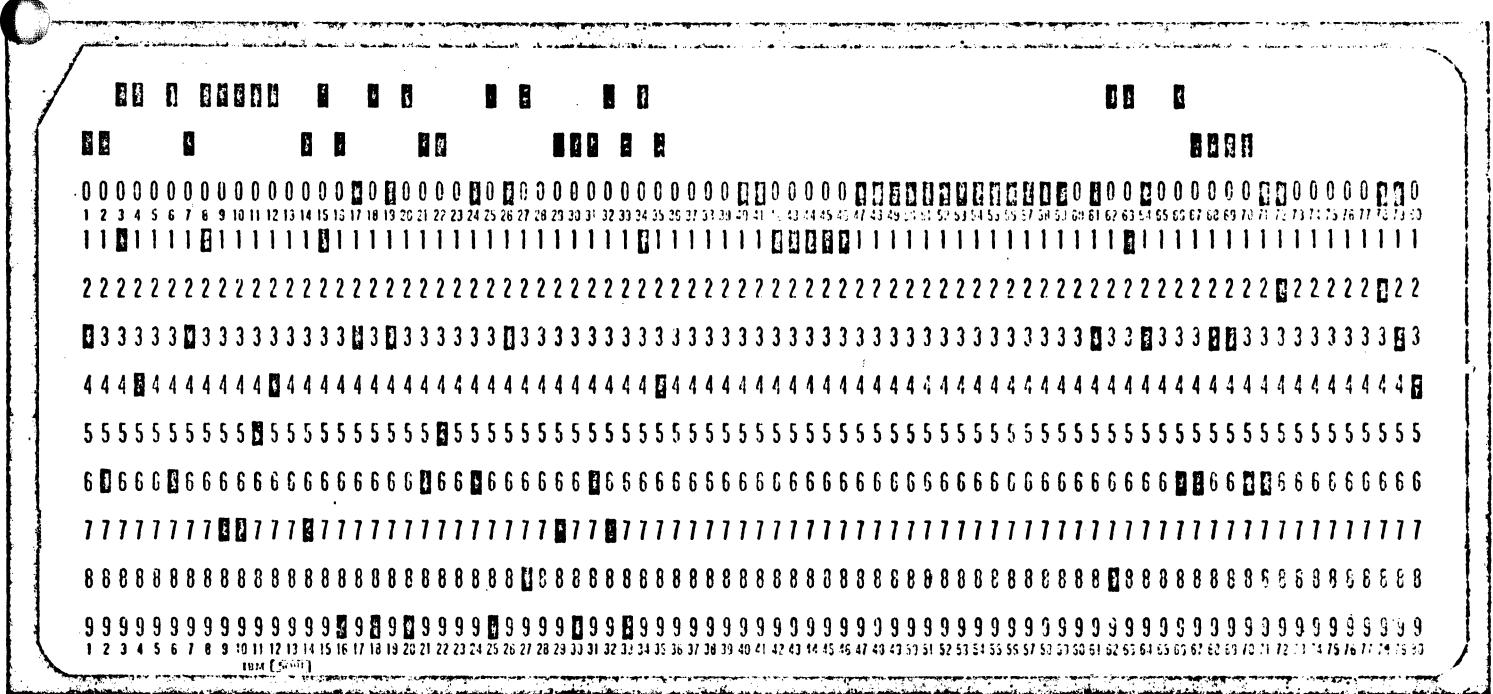

ST2

ST3

ST4 CARD EXAMPLE

Card Column

1-39

Comments

40-59

Flag positions which represent the possible 20 partitions of the system. A one (1) in one or more of these columns will result in the program following the ST4 card being loaded into the corresponding partition. i.e., column 41 = partition 1, 42 = partition 2, etc. A zero (0) will not load the corresponding partition.

60-77

Comments

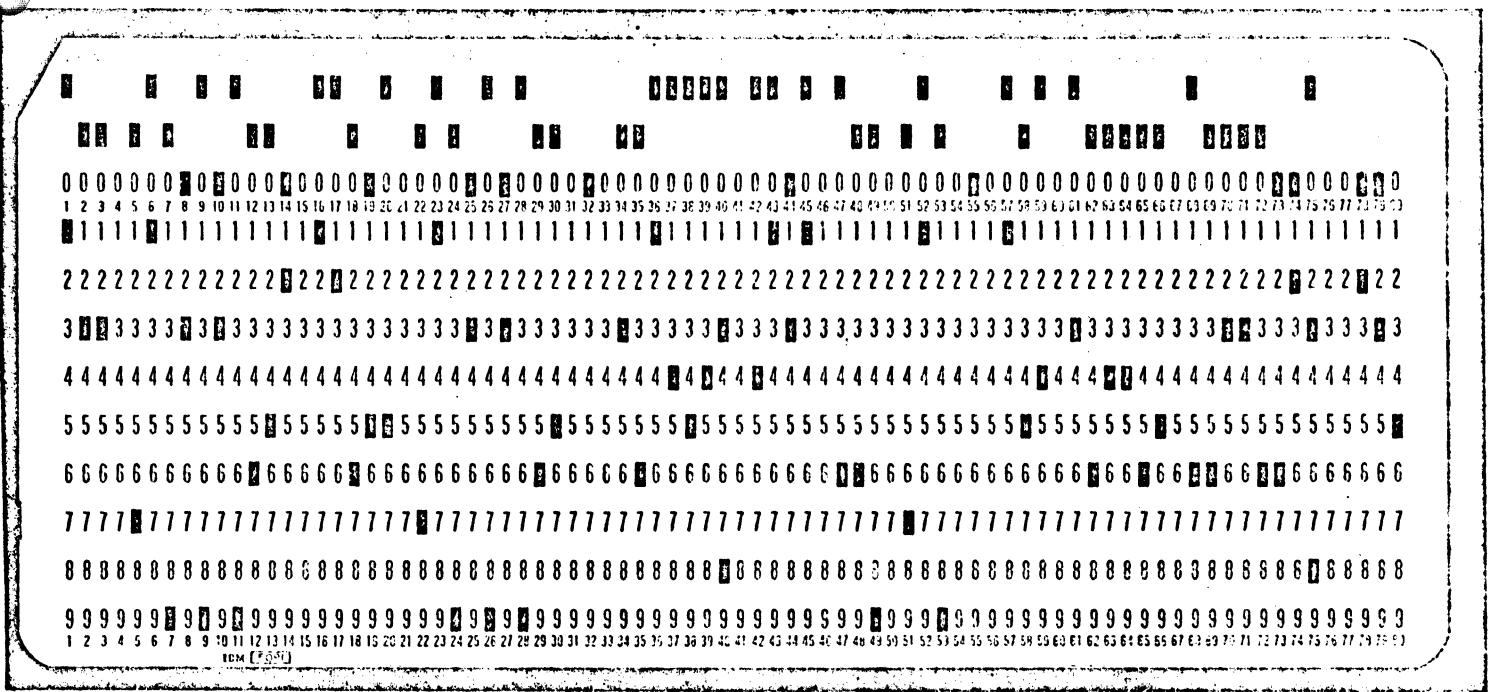

78-80

ST4

Contents

Note: Partition 0 cannot be loaded by the ST4 card. Non-existent partitions will be bypassed without generating load errors. Existing partitions not requested to be loaded will be automatically loaded with a cycling instruction only in position 0 of the partition.

ST5 CARD EXAMPLE

Card Columns

1-77

Comments

78-80

ST5

Contents

Note: The ST5 card is used as a flag to the CHLOE Loader to state that all available partitions above zero have been loaded, and that the program following the ST5 card is to be loaded into Partition 0 and Common Core.

ST6 CARD EXAMPLE

Card Columns

Contents

- | | |
|-------|--|
| 1-5 | S card execution address for this card. |
| 6-10 | Not Used |
| 11-50 | Instructions used by CHLOE to print the message in card columns 61-70 to show that program loading is complete. |
| 51-55 | The starting address of Partition Ø. This must be the first five machine language characters of an unconditioned branch to the starting location desired. This address is available for user modification. |
| 56-60 | Not Used |
| 61-70 | Message to be printed signifying loading complete. This message may be user modified. |
| 71-74 | Constants used by CHLOE. |
| 75-77 | Not Used |
| 78-80 | ST6 |

Note: The ST6 card signifies that loading is complete and automatically executes Partition 0. The ST6 card contents is different for the Basic CHLOE and the DMF CHLOE. The example used is the ST6 for the Basic CHLOE.

PROGRAM LOADING

SECTION 3

MDTS Program Loading

The MDTS program may be loaded in one of four ways depending upon the media and method used for program storage.

- A. Program stored using the Disc Management Facility librarian functions.
- B. Program stored on disc utilizing a special MDTS bootstrap.
- C. Program stored on magnetic tape utilizing a special MDTS bootstrap.
- D. Program stored on other media such as cards or paper tape.

The CHLOE (CHannel LOad Execute) multipartition system loader is used for each method of loading.

- A. Program stored using the Disc Management Facility librarian functions.
 1. Initiate the Conversational Loader by securing a LOAD condition in partition zero on the attached device zero console and completing the subsequent read from the console by either:
 - a. Depressing the ENTER key on the workstation.
 - b. Simultaneously depressing the Control key and the Question Mark key on the 7102 Communication Terminal.
 - or c. Keying in ten zeros on either device.

The Conversational Loader will respond with: A) ENTER PROGRAM NAME

2. Key in MDTS and complete the read from the console by either:
 - a. Depressing the ENTER key on the workstation.
 - or b. Simultaneously depressing the Control key and the Question Mark key on the 7102 Communications terminal.

The CHLOE loading messages and appropriate system messages will print as the program is loaded.

- B. Program stored on disc utilizing a special MDTS bootstrap.

1. Secure a LOAD condition in partition zero on the attached device zero console.
2. Key in the following special bootstrap:

0000100000

The CHLOE loading messages and appropriate system messages will print as the program is loaded.

C. Program stored on magnetic tape utilizing a special MDTs bootstrap.

1. Mount the program tape on tape drive 2.
2. Secure a LOAD condition in partition zero on the attached device zero console.
3. Key in the following special bootstrap:

2001000080

The CHLOE loading messages and appropriate system messages will print as the program is loaded.

D. Program stored on other media such as cards or paper tape.

1. Ready the program in the appropriate reader.
2. Secure a LOAD condition in partition zero on the attached device zero console.
3. Key in the following special bootstrap:

d001010080

where "d" is the reader device number.

The CHLOE loading messages and appropriate system messages will print as the program is loaded.

CHLOE Loading Messages

A. Normal Loading

SW NRM

This message indicates that the CHLOE loader is beginning to load remote partitions. If a subsequent message does not follow immediately, verify that the MODE SELECT switch on the display panel is turned to NORM.

C SIZE aaaa QLIM bb INPXA cccc

This message indicates the completion of the common core evaluation.

"aaaa" indicates the amount of core allocated to common. (0000=10K)

"bb" indicates the number of blocks allocated to the common data queue.

"cccc" indicates the data queue maximum block pointer.

PAR LOD Øxxxxxxxxxxxxxxxxxxxx

This indicates the partitions requested to be loaded.

x=Ø indicates no request.

x=1 indicates a request.

Non-existent partitions may be requested for loading and will show in this message. Existing partitions not requested will be loaded with a cycling instruction.

xxxxxxxxxx (Load Complete Message)

This message is printed on completion of reading and executing the ST6 card of the CHLOE Loader. The message may contain from one to ten System Ten characters, and is a part of the ST6 card itself in columns 61-70. (See ST6 card Example Section 2 page 13 of this manual.)

B. Error Messages

Three error messages are:

1. "RD ST" to indicate a read status error.
2. "C SIZE NOT" to indicate insufficient common area available according to CHLOE card number 0001.
3. "LOAD REQ ERR" to indicate a load request error of either not a 0 or 1 in columns 40 thru 59 of the CHLOE ST4 card, or a request to load a program in a partition already loaded.

System Messages

A. Program Identifier

The system will first print a program identifier message. The identifier format is:

"SINGER-FRIDEN MDT SYSTEM"
ppvll-yyddd
pp = Program Mnemonic
vv = Version Number
ll = Level of Distribution
- = fixed dash
yy = Year
ddd = Julian day

B. Partition Check-In

Each partition properly loaded will report in with ATT09.
The ATT09 format is:

ATT09 UØSQPØØnnr

nn is the partition number
r is a residual character

C. Special Messages

If a clock partition is present, a Clock Stopped message is printed at the initialization of the system. The Clock Stopped message format is:

CLOCK STOPPED AT dddhhmmss

ddd = Julian Day
hh = Hour
mm = Minute
ss = Second

To initialize the clock, follow the console instructions specified in item H, Section 5, page 2.

CONSOLE MESSAGES

SECTION 4

CONSOLE MESSAGES

The 7102 Communications Terminal is attached to partition zero and various messages are passed to it from the other partitions via a common buffer. Partition zero examines this message buffer and prints it when filled.

Messages are 27 characters long formatted with a standard 5 character tag followed by up to 22 characters of data relative to the tag. For example, a disc read error will have a 5 character tag followed by the 6 character disc address where the error occurred.

The messages are separated into three categories; Attention, Warn, and Error. In general, the "Attention" messages indicate the completion of a command such as a transmission to the host computer. The "Warn" messages mean that something did not happen as expected, such as an attempt to delete a non-existing account number from the credit file. The "Error" messages indicate that an error has occurred such as a disc I/O error.

ATTENTION

ATT01 - This message indicates a successful transmission of a transaction file to the host computer. Accompanying the ATT01 tag is a 14 character code number for the data just transmitted and a 6 character count of the number of transactions sent. The code number must be entered for all subsequent resends of these transactions. The format of the ATT01 message is:

ATT01 bbbbbbeeeeepp ccccc

bbbbbb = beginning disc address for this transaction file.

eeeeee = ending disc address for this transaction file.

pp = the picture address. This is the even sector of an even/odd pair in the home track that contain the picture data for this transmission.

ccccc = the character count of the number of transactions sent.

ATT02 - This message indicates the receipt and completion of an option 6 command from the host computer. This means that the credit file has been cleared and reinitialized and the system is ready to receive a new credit file. This message will appear when initializing a disc pack without host involvement. (See ATT05.)

ATT03 - Attention 3 indicates the completion of the building of a credit file or the completion of a series of on-line updates to the credit file. Accompanying the ATT03 tag will be a 6 digit count of the account numbers now on the credit file followed by 12 digits indicating the disc address for the beginning and ending of the credit file. The format of the ATT03 message is:

ATT03 ccccccc bbbbbbeeeeeee

cccccc = count of the account numbers now on the credit file.

bbbbbb = beginning disc address of the credit file.

eeeeee = ending disc address of the credit file.

ATT04 - This message occurs in standard MDTs Systems upon normal loading of the software in the System Ten partitions. It is a request for operator determination of the status of the disc pack mounted on drive number zero. Only one of the following replies will be accepted by the MDTs System before system loading can complete:

NRMLD This reply implies that a disc pack that has been previously initialized to MDTs System specification is mounted on disc drive zero (see MDTs System Initialization Program Documentation).

DINTL This reply states that the disc pack on drive zero has not been initialized to MDTs System specification. The MDTs System will then proceed to request system parameters (see ATT05).

ATTENTION (CONT)

ATT05 - This is a request for entry of MDTS System initialization parameters. It is generated when DINTL is used as a response to the ATT04 message. If the MDTS System Initialization Program is not available to the user, the required parameters may be entered on the console device at this time.

NOTE Extreme caution is advised if MDTS System initialization parameters are entered via the DINTL and ATT05 request as the parameters are not edited for validity and integrity. The support program, MDTS System Initialization Program, should be used for parameter entry to insure accurate system initialization.

Parameters entered via the ATT05 request must be in the exact order they are presented in the FILCON description in Section 7 of this manual. When the last character has been entered, the MDTS System will display them on the next console print line and it will accept the parameters only if the letter "Y" is entered on the console device. If any other reply is entered, such as "N", the MDTS System will repeat the ATT05 request for parameters.

When the parameters are accepted, the MDTS System will commence clearing the disc area specified for use as the credit file area. (see ATT11) and initialization is complete.

ATT06 - This is an indication of a break in the normal communication sequence with the host. The format of the ATT06 message is:

ATT06 fff aaaa iiidddii

fff = 1 to 3 digit (as applicable) of the function command that was active.

aaaa = the core address of the I/O instruction which faulted (timed-out).

iiidddii = the actual instruction which faulted.

ATT07 - This indicates the completion of the ENDAY option. Accompanying the ATT07 tag will be two digits indicating the new day number. The format of the ATT07 message is:

ATT07 dd

dd = the new day number.

ATT08 - Attention 8 indicates an orderly close of the system. This message must follow a "SYSDN" command. It means that this disc is closed and all parameters updated appropriately. No terminal transaction or host commands will be accepted.

ATTENTION (CONT)

ATT09 - This indicates a pass through position 0000 of a partition. The 10 characters at position 40 of the partition are also reported. The format of the ATT09 message is:

ATT09 kaaalppppd

k = size (K) of the partition.

aaal = address of the instruction +11 (+1 if an I/O being executed at the time of the check. The zone bits of characters "aaa" indicate the condition code Flip-Flops of "CARRY", "MINUS", and "ZERO" and the zone bits of character "l" indicates the location of the instruction (partition or common)).

If there was no ACU check condition, "aaal" have no relevance.

pppp = the partition number where the recovery occurred.

d = the last device that received an acknowledgement for service by the processor.

ATT10 - Indicates completion of host initiated reset of any communications routines in progress.

ATT11 - This message indicates that the system has been directed by the operator or communications to clear the negative credit file. The credit file cannot be accessed until an "ATT02" message is typed on the console monitor which indicates the completion of the clear function.

ATT12 - This message informs the operator that the ENDAY command cannot be automatically serviced because one or more point-of-sale terminals is not closed. The complete message format is:

ATT12 ALL TERMINALS NOT CLOSED

*xx*yyyyyyyyy*

(More than one line may print, as required. See description of STATE command (Section 5) for "xx" and "yy..." definition).
REPLY YES TO OVERRIDE OR NO --

The operator may reply "YES" and the condition will be overridden. Any other response such as "NO" will cause the MDTs System to resume normal cycling, having taken no action.

WARNING

WRN01 - This message indicates the approaching end of the transaction file. It is accompanied by a two digit number indicating the number of tracks left before encountering WRN02.

WRN02 - This message means that the last available track has been reached, and any data in queue is logged on disc. The disc will accept no further transactions until the system has received an option Ø command from the host and sent the transaction data. The WRN02 tag is accompanied by 2 digits indicating the number of tracks reserved to write data left in queue when encountering WRN02. Credit authorization will continue, but transactions will be blocked.

WRN03 - This indicates an attempt to delete an account number not on the file. It is accompanied by the account number received. The number is ignored. Normal processing continues.

WRN04 - This indicates an attempt to change the credit status of an account number not on the file. The number accompanies the tag and is ignored. Normal processing continues.

WRN05 - Warning 5 means that an attempt to add to the credit file has not been successful because the overflow area is full. The number accompanies the tag and is ignored. Normal processing continues and other additions may very well be successful because not all additions will be going to the overflow area.

WRN99 - Warning 99 is generated by the occurrence of a track check while trying to read the disc. The sector address is printed with this warning. If the second read of the sector yields the same result, the disc address printed is incremented by one and the read tried again. This logic is used because the disc arm position cannot be program verified. The procedure of incrementing the disc address allows access of the desired track only, and in the event of parity/track checks on all sectors of the given track, a loop is entered preventing access of the disc until operator intervention. This condition is detected by unending "WRN99" messages on the console device for the same track.

ERROR

- ERR01 - Error 1 is a parity error or LRCC miscompare on a disc I/O. The program will retry ten times and, if there is no change in status, report ERR03 for the same address before beginning an error recovery procedure. The disc address accompanies the ERR01 tag. The condition code is a 1.
- ERR02 - This message indicates the transmission of invalid characters for the credit file. The data sent accompanies the ERR02 tag. The data is ignored and normal processing continues.
- ERR03 - Error 3 indicates a bad sector on a disc I/O. If the instruction was a "WRITE", hardware will have written a bad sector blot on the sector. If the instruction was a "READ", hardware would have detected a bad sector blot from a previous write. Subsequent "READS" will always return a bad sector status. Subsequent "WRITES" may be successful, at which point the sector is available for normal use. The condition code is a 3.
- ERR04 - This message indicates that a disc I/O has returned a "drive not available" status. The system waits at the I/O instruction until the drive becomes available. The disc address accompanies the ERR04 tag. The condition code is a 4.
- ERR05 - This will indicate the recovery of bad data from the disc during a send of the transaction file to the host. The data on the disc is checked for the terminal's transmission start code "P" and a valid 1, 2, or 3 block count.

The ERR05 tag is accompanied by the disc address being accessed and the invalid portion of the data on the disc.
- ERR06 - This message indicates that data in queue is in error. The validity check here is on the block count. The data is reported with the ERR06 tag and ignored. Normal processing continues.
- ERR07 - This indicates that no proper data was found in the file parameters of the picture which had been requested by the host as a resend. The host computer will receive a normal '*END' message and the ATT01 message is reported at the console with the non-numeric data following the ATT01.
- ERR08 - This indicates that improper data has been entered from the console during a TRACE - DDUMP or service request.
- ERR09 - This error occurs when the Host computer has attempted to transmit credit numbers with the transmission length either exceeding or being less than the required number of characters expected. The MDTs System will "NAK" the Host and attempt to reread the transmission. If a second failure is encountered the transmission is accepted and discarded as invalid. Those characters received from the transmission are printed with the error notation.
- ERR19 - This indicates an attempt to communicate from another computer without the proper identification. The identifier of the other computer is displayed following the ERR19 tag.

ERROR

CLOCK STOPPED AT *DDDHMMSS -

This message indicates that the software clock has stopped and no further transactions will be accepted by the system from any terminal.

REENTER TIME -

This message indicates that the previous time entry did not fall within the proper parameters.

WORKSTATION COMMANDS

SECTION 5

WORKSTATION COMMANDS

Various commands applicable to the MDTs System can be entered through the console device to either follow the path of the system, or to alter the data flow through the system. These commands are entered only after the program is loaded and operational by obtaining a Service Request.

At the time the Service Request is honored by the System, type one of the following five (5) character commands.

STATE
PRINT
ENDAY
DDUMP
SYSDN
SYSUP
TRACE

The above commands, their use, and formats are discussed as follows:

STATE - This command is used to determine which MDTs Terminals are active to the System. The format is:

*xx*yyyyyyyyyy*

xx - Partition Number

yyyyyyyyyy - Ten possible terminals which may be attached to this Partition. If the Terminal relative to the position shown is active a 1 will be displayed. If inactive or nonexistent the relative position will be Ø.

PRINT - This command will print a series of internal accumulators for purposes of monitoring the system. The format is:

*NUQnn*INPaaaa*OPTcccc

nn = Number of Transaction blocks in the queue.

aaaa = Address of the next available queue location for terminal use.

cccc = Address of the next transaction in the queue to be written to the disc.

ENDAY - This command will cause the logical day number used in recording point-of-sale terminal transactions to be incremented by one. This has the effect of ending one logical days transactions and causing all subsequent terminal activity to be recorded against the next logical day (see DY, DAYNRT, and DAYNRD descriptions in Section 7 of this manual).

The day numbers used may range from 01 to 99 and will start at 01 again after 99 is reached.

ENDAY-(CONT)

Successful completion of the ENDAY functions is signaled by the ATT07 message. However, if all point-of-sale terminals are not in a "closed" state, the ATT12 message is reported on the console device. Completion of the ENDAY function will also block all further activity of the MDTs System and its terminals until the SYSUP command is entered or the System is reloaded.

- DDUMP - This routine will dump the disc to the device required in increments of 100 character sectors. Servicing the DDUMP command, the System will wait for the proper parameter to be entered. The parameter format is:

aaaaaadsssss

aaaaaa = The beginning disc address.
d = The output device (\emptyset is the console device).
sssss = Number of sectors to be dumped.

If the parameter above is not all numeric, "ERR08" is generated and displayed on the console device. See Section 4 for a discussion of the Console Messages.

- SYSDN - This command is used to orderly shut the System down. After normal completion of the SYSDN command, the System will report completion (See ATT08 in Section 4) and block all terminal activity until the SYSUP command is entered, or the complete System is re-loaded.

- SYSUP - This command is used to open the System after the completion of the SYSDN command. The System will report the completion of the command by printing the System Status Sector on the console device.

- TRACE - This command allows the selective dumping of transactions to the console device. The operator may specify the terminal, the number of characters to be printed, the beginning and ending disc address. The routine searches the specified disc area, prints each transaction logged by the terminal being traced and its related disc address. The System returns to normal cycling when the operation is complete.

Servicing the TRACE command, the System will wait for the proper parameter to be entered. The parameter format is:

ppccccbbbbbeeeeeee

pp = Partition Number, 01-19
i = Terminal, 0-9
ccc = Number of characters to be printed.
bbbbbb= Beginning disc address for the TRACE.
eeeeee= Ending disc address.

TRACE-(CONT)

If the parameter above is not all numeric, "ERR08" is generated and displayed on the console device (see Section 4).

DISC ORGANIZATION

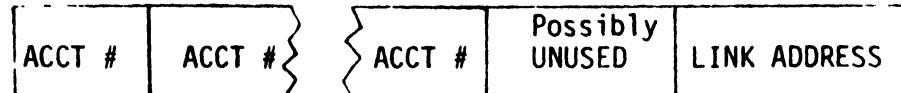

SECTION 6

DISC ORGANIZATION:

The disc is organized to efficiently contain three important divisions:

1. System track
 2. Credit file
 3. Transaction file
1. The System Track contains key data relative to the credit and transaction files. The first sector contains the System Status Sector; the next contains labels for convenient isolation of data fields when printing the System Status Sector. (See SYSSS in Data Buffer Descriptions.) The remainder of the track contains daily pictures in sector pairs. (See TRMZAD and TRMZBD in Data Buffer Description.)
 2. The Credit File is stored on disc at locations specified at initialization.

Each Sector is organized as follows:

Each account number is randomized to a sector in the credit file. If more account numbers randomize to a sector than the sector can hold, linkage will be established to an overflow area.

3. The transaction file location is specified at disc initialization. It is a dynamic file to all transactions. A particular day's transactions are logged consecutively as they enter the system. They begin at the first of a track and end at the last transaction logged prior to a host computer's signal to send transactions or the manual closing of the system, SYSDN or ENDAY. The pointers for a day's transaction are logged in its picture on the home track.

DATA BUFFER DESCRIPTIONS

SECTION 7

DATA BUFFER DESCRIPTION

This is a description of key data areas used in the MDTs program. This description is an aid to understanding processing details and tracing machine malfunctions.

SYSTEM STATUS SECTOR (SYSSS):

The System Status Sector contains a series of data fields relative to the current status of the system. It is stored in common and kept on the first sector of the home track (HOMAD) on disc. Any change in the System Status Sector in core will activate a routine to restore the new SYSSS back on disc. Closing the system with a SYSDN or ENDAY command will write the SYSSS on the disc being closed, and opening a system with a SYSUP command will read the SYSSS from the new disc into core.

The SYSSS is detailed as follows:

CURPIC - This is the 6 digit disc address of the current picture being processed. It refers to a picture in the home track. The picture referenced contains the data relative to the actual processing being done. It is described under the heading "TRMZA".

For example, a CURPIC of 000158 means that sectors 58 and 59 of track 1 contain the data relative to the current processing point. Closing the system at this point would write the TRMZA buffer into 000158 and 000159 and update CURPIC to 000160. The picture addresses wrap-around from the end of the home track, 000198 and 000199, to 000102 and 000103. The System Status Sector is stored at 000100.

NXPIC - This is 6 characters denoting the day indicator and the basic disc address of the next picture to be retrieved to send to the host. The first two characters are the day and the remaining four are the disc address when preceded with the first two digits of HOMAD. Upon receipt of a signal to send, the data in this picture is read into TRMZB for processing.

QBLOCK - This is a 1 character field which blocks the addition of data to the queue. It is activated in a WRN02 condition. Normal queue fills will occur with a value of 0.

NX SND - This is the 6 character address of the next data to send to the host. It is incremented during the sending process, but is always set by the limits indicated in the data referenced by NXPIC prior to a send.

FILCON - This is 61 characters defining various system parameters. FILCON is loaded during disc initialization according to the following format:

FIRAD - This is the first address of the transaction file.

FIZLIM - This is the physical limit of the transaction file.

DL1 - This is a 2 character constant entered at initialization indicating the number of tracks reserved for transactions following a WRN01 condition.

DL2 - This 2 character field indicates the number of tracks reserved for data in queue following a WRN02 message.

DL2 must always have a smaller value than DL1 and must specify the number of tracks necessary to contain an entire queue.

TTDRST - This 2 character constant is used to reset a counter to allow an efficient use of the TTD message during communications. Its value should be determined on the basis of machine configuration (number of terminal partitions) and expected communications timing (on-line with terminal activity or off-line).

PRIME - This is a 6 character prime number indicating the number of sectors used by the credit file. PRIME is used in the randomizing routine to determine the actual disc address of account numbers.

STADR - This is a 6 character disc address indicating the beginning of the credit file.

LOVFL - This is the 6 character disc address indicating the end of the Credit File Overflow. It must be at least 10 sectors beyond STADR + PRIME. Any sector in the normal file (STADR to STADR + PRIME) which overflows will log into this area.

NXLNK - This is the address of the next available address in the overflow area. It is initialized at STADR + PRIME. A SYSDN preserves NXLNK relative to the data logged on this disc. Option 6, Credit File Clear, resets it.

BDLNK - This is the beginning of a save area in the bottom of the overflow area that will be used for any bad sectors encountered in the credit file. It is set at initialization time.

- NXTBD - This is the 6 character address pointing to the next sector available in the bad sector save area.
- LDATA - This is a 3 character field indicating the last account number in the credit file disc I/O buffer, DATA. See the description of DATA for the method of deriving LDATA.
- ACLNT - This is a 4 character field for the account number length. The first two digits are the minimum length and the last two digits are the maximum length which will be accepted and processed. The maximum length includes the check digit.
- DYNLM1 - This is a 6 character address indicating the first dynamic limit. It is calculated using DL1 and NX SND. This is the first dynamic limit which, if reached, will create a WRN01 condition. It is recalculated each time a picture is sent.
- DYNLM2 - This 6 character disc address is the second dynamic limit. Encountering it will create a WRN02 condition. It is recalculated each time a picture is sent.
- CICNT - This six character field is the count of credit numbers currently on the credit file.
- DY - This 2 character field contains the current day indicator.

CURRENT PICTURE BUFFER (TRMZA):

- TRMZA - This is a 10 character field preceding TRMZAD for addressing purposes. Its contents do not relate to the picture; only its length. The last digit must be a zero.
- TRMZAD - This is the first 100 characters of a 180 character field indicating which terminals are currently or have been active for this picture.
- TRMZBD - This is the remaining 80 characters of the table begun in TRMZAD. Each terminal used during this picture has a 1 set in the table. Terminals not active are flagged zero.
- FIRSTD - This is the first sector of the picture. Transactions sent to queue are logged on disc beginning at this address. When the picture is closed, this address will become the transmission start address in TRMZB.
- NXTAD - This is the address of the next sector to be written. When the picture is closed this becomes transmission end address.
- TRCNT - This is the count field for logging transactions on disc.

DAYNRD - This is the day indicator for this picture.

SEND PICTURE BUFFER (TRMZB):

TRMZB - These 10 characters are used for addressing only. The last character must be zero.

TRMZAT - These 100 characters begin the 180 character table to indicate which terminals were active for the picture being transmitted.

TRMZBT - This is the remaining 80 characters of the table. This table and the next three fields are read from the Home Track at the picture being sent. Each "1" in the table indicates a terminal that transmitted a message to the line concentrator.

TRSTT - This is the transmission start address. It corresponds to FIRSTD in TRMZA for this picture.

TRLIM - This 6 character address is the transmission limit. It is determined by the NXTAD field in TRMZA.

TRCNT - This 6 character field is used to count the transactions sent to the host. A transaction is defined as a transmission from the MDTs terminal to the queue. A single sale taking 400 characters requires 2 transmissions from the MDTs terminal and logs as two transactions.

DAYNRT - This is the day indicator which this picture was built to.

INTERMEDIATE TRANSMISSION BUFFER (MBUFF):

MBUFF - A total of 300 characters is used to hold up to three blocks of data for a single transaction. During a send of the transaction file, MBUFF is filled with one transaction only. Control then passes to a stuffing routine which packs and formats the data in the transmission buffers.

MBUFF's first 8 characters are always "ccdb111P" defined as follows:

"cc" is the partition, or channel, to which this terminal is attached.

"d" is the device number assigned to the terminal, determined by the connectors to which it is attached on the partition.

"b" is the number of 100 character blocks (sectors) taken by this transaction in storage on the disc.

"111" is the actual length of the message counting the 7 character prefix.

"P" is the beginning code of the transaction.

The last character of MBUFF is used for a full - not full flag. The SENDTR procedure will put 1 complete transaction in MBUFF and flag it full. The STUFF procedure will take it out and flag it empty.

COMMUNICATION BUFFERS:

This system is double buffered, having one Communication buffer in Common and the other in the SCA Partition. Depending on the function being acted on, the buffers may be either Send or Receive buffers. The act of send and receive cannot occur simultaneously, thus the dependency on the function being performed.

Associated with the buffer in Common are two flag fields of four (4) characters each. One flag pertains to the common buffer, the other to the SCA buffer. The first character of each field is a flag stating whether or not the associated buffer is full or empty. The remaining three positions of each is the number of characters in the buffer.

TERMINAL BUFFER (INBUF):

Data comes from the terminal to this buffer before being logged in queue. This buffer is located in the partition. The terminal transmits a communications character, a "P", and then a text. The communications character is removed so that INBUF effectively begins with "P" and is followed by text.

CREDIT AUTHORIZATION DISC I/O BUFFER (DATA):

DATA is a 94 character field with a 6 character link address used for disc I/O during credit operations. It contains the account numbers relative to a particular disc address. The account numbers are packed into each sector depending upon the account number length. For example, a 13 digit account number length will allow 7 account numbers in 94 characters. An 8 digit account number will allow 11. LDATA, mentioned in SYSSS, points to the last account number. LDATA is 078 in the 13 digit example, 680 in the 8 digit example.

The 6 character field called LNKAD is used to link a sector to the overflow area when the sector becomes full.

CLOSED TABLE:

The CLOSED TABLE is a 20 position table preceded by a zero (CLOFLG) that is used to indicate which partition is utilizing shared routines. It is a software flag used to protect shared routines and data buffers during partition switching.

The table must contain all zeros before a partition can request control of the routines. When a partition assumes control, a 1 is moved into the table position corresponding to the partition number. To release control, a zero is moved into the table position which corresponds to the partition number.

BRIEF DISCUSSION OF SHARED ROUTINES

SECTION 8

BRIEF DISCUSSION OF SHARED ROUTINES

- SEND1** - The SEND1 entry point is the master control of the system. Entry is made here from each terminal partition that does not have a service request. System Ten functions are then selected on a priority basis giving queue to disc first priority, then, in order on-line credit file changes, transaction file transmission and rebuilding the credit file. If no function is pending, the system returns to a check of a service request and switches partitions.
- SENDQ** - The SENDQ entry point writes data in blocks of one, two, or three to the disc. Illegal data is ignored and a message passed to the 7102 Communications Terminal. Queue pointers are updated and reset to the beginning if the queue is empty.
- SENDCK** - This is the entry point for sending data to the host computer from the Transaction File. It is used for normal end of day sends, resends, and on-line sends. The data is read from the file as a single transaction for packing in the transmission buffer.
- STUFF** - The STUFF entry point is used after reading a transaction from the file. It formats the data properly for transmission.
- HOWDY** - HOWDY writes transactions from the queue to the transaction file on disc. Disc I/O status is tested and errors reported and proper recovery routines executed.
- BIEN** - The BIEN/ADIOS routine increments the file disc address during a transmission of the transaction file to the host. It provides for automatic wraparound of the physical limits of the files area.
- OHELL** - This routine reports disc I/O errors encountered during a transmission. Error recovery is handled in the calling routine.
- HELLO** - This routine reads a single transaction into memory. Data is validated before it is allowed to be formatted in the transmission buffers and errors are reported at the 7102 Communications Terminal.
- UPNDWN** - The UPNDWN routine will set the dynamic limits of the transaction files area on disc. A warning will be sent when data being written from queue reaches a user specified number of tracks from a disc full state. A warning and a halt will occur when the data reaches a second user defined number of tracks from a full condition. (See WRN01 & WRN02) Data in queue will be logged on disc, host computer commands will be accepted, and credit inquiries acknowledged, but no additional transactions from terminals will be accepted until the file is emptied.

CLOSIN - This routine places the current picture on disc. It then sets up new tables for a new day and writes it on disc. This routine is accessed by an orderly close procedure.

WELCUM - This routine updates the disc address while writing data from the queue. A picture of the pointers is logged on disc at each track change in the transaction file. Checks are made for dynamic limit overflows and appropriate warnings issued at the 7102 Communications Terminal. This routine also checks the physical limits of the files area.

SNAPIC - This routine records a picture of the status of the transaction file at each track change as well as a normal closing procedure.

PORTRT - This routine is used to record the System Status Sector on disc any time it changes.

GETSYS - This routine reads the System Status Sector into core during initialization or reload.

GETPIC - This routine will retrieve the current picture from disc and set up the tables necessary for operation. It is used for normal loads, and initialization.

It is also used to retrieve the picture to send to the host during a poll for transaction data.

DSOF-DSBAD - These routines report disc I/O errors on the workstation.

The disc condition codes are:

A. CC = 1 means parity check.

B. CC = 4 means disc not available or fault.

C. CC = 3 means bad sector or flag.

TATTLE - This routine reports a pass through position zero of a partition. This normally corresponds to a hardware (ACU) check. Accompanying an ATT09 tag will be the 10 characters in position 40 of the partition (See ATT09 discussion.)

OLUP - This entry point is made on a host signal for on-line updates. Transmitted data is validated, the type of update requested is determined, and appropriate routines are called in.

FLBLDA - This is the entry point for building a new credit file. The input buffers are cleared and reset after the entire credit file area is cleared to zeros. A message signalling the end of the required option is passed to partition zero. The system then awaits account numbers which follow on a host command. The on-line entry point is then used to complete the file building operation and the number of account numbers logged on disc is reported at the workstation.

- CIREP - This routine checks the credit status during a credit inquiry from the terminals. The status found on disc is tabled with the current device. When returned to the partition, a check is made to verify that the device which initiated the request is actually the device being answered. If the account number was not on the file, "NOT HERE" code is returned to the terminal. If the number was found, a user specified digit is returned for display to the terminal.
- RNADR - This routine determines the disc address for each account number, giving a smooth distribution for the credit file.
- SEARCH - This routine searches the credit file for a specific data pattern. This pattern is the account number during an inquiry, change or delete and zeros during additions. It replies with a digit or a "NOT HERE" code.
- ACCADD - This routine adds a data pattern to the credit file. This pattern is the account number during file building and updates. It is zeros during deletes. The search routine finds one pattern on the file, and this routine writes a second pattern in its place.
- RERE - This routine allows for a read in the overflow area during credit file operations should it become necessary.

DETAILED DISCUSSION OF SUBTLE
PROGRAMMING TECHNIQUES

SECTION 9

DETAILED DISCUSSION OF SUBTLE PROGRAMMING TECHNIQUES

This section explains the reasons for, and operations of various addresses, instructions, and techniques used in the MDTs Disc Credit Authorization Program.

BASE ADDRESSES:

A series of base address labels are defined in the low order of COMMON. They are BAZ, BAS1, BAS3, and BAS4. These labels give a base address for instructions. Data in the low order of COMMON is protected and these labels do not in any way affect this protected area. They simply provide a base address for an instruction. For example, the instruction labeled MARK in the STUFF routine does not move data to zero in common as it superficially appears. The preceding instructions have modified MARK so that the B operand, BAZ, simply provided a common flag for the "Move To" address.

WORK AREA IN 300 (C):

Twenty positions, 300 to 319 in common, contain work areas and loader set constants that must be resident in these locations.

MODIFIED BRANCHES:

It is necessary at several points to modify branch instructions. The statement labeled FSTONE in the SENDTR entry point is a good example. The first signal to send transactions enters at SENDTR. MBUFF's flag will be zero (it's empty) so the condition code following SENDTR will be 1. The first half of the branch at FSTONE is not satisfied and the second half is pulled. Initially, the B Modifier is zero, a fall through condition code. This allows a series of reset instructions to be executed one time only.

This branch is made unconditional at RSFST for the remainder of the transmission and is reset to a fall through at its completion.

These instructions are also reset during the operation of a SYSUP command to insure an initial condition upon starting.

COMMON ADDRESS MODIFICATION:

Addresses in COMMON carry a high bit which is arithmetically negative. Incrementing a COMMON address, therefore, requires a subtract operation. The instruction following MARK in the STUFF routine is an example. The field STUFFA contains a TBUFF address. It is incremented to the next available position for a transaction by subtracting a positive character count. Subtracting (+5) from (-10) gives (-15).

CONSTANTS IN INSTRUCTIONS:

If the first half of a branch instruction is satisfied, the second half is never pulled. If the first half is an unconditional branch (code 5 or 8) it is always satisfied. It is therefore, possible to utilize the remaining 5 positions of the instruction for data or work areas.

ACU CHECK CONDITION:

On occasion, the System Ten hardware forces the system to execute an instruction at position zero of a partition. At position zero of each partition, therefore, is an unconditional branch to a routine labeled TATTLE. This routine reports an ATT09 message to the workstation and returns to a selected restart address in the partition. The restart address is conveniently stored in positions 6-9 of the partition.

PARTITION POSITION SETTING IN CLOSED:

Each partition contains a 4 character field which is initialized at the address of a routine's-in-use table labeled CLOSED. After loading, the actual value of this field is set to its corresponding position in the CLOSED table. This is necessary so that a partition claiming the routines can release them under ACU check conditions without affecting the status of other partitions.

For example, suppose CLOSED begins at 2000 (C). Upon loading, the program in partitions above 0 will modify the address by adding the number of the partition to the base address of CLOSED. Partition 5, for example, will now have an address of 2005(C) while partition 11 will have an address of 2011(C), and the shared routines will be claimed or released by moving a 1 or 0 to the specified address.

INSTRUCTION REPLACEMENT:

Execution of partition zero begins at 0300 (P). Upon loading for the first time, position 0300 contains a branch to LOADST. It is later replaced, and subsequently operates with a branch on service request. Compare ROX to XROX.

During initialization of a disc, it is necessary to simulate an option 6, credit file clear. During a normal load, it is necessary to clear PSFLAG, but execution of the normal load routine following a disc initialization cannot reset PSFLAG, therefore, a series of instruction replacements must occur.

In the initialization routine, an instruction labeled DIDY is defined. When executed, it will move an instruction labeled DITY from SEND1 to an instruction labeled DUTY in the normal load routine. When initializing a disc, DUTY is replaced with DIDY. When the normal load routine is executed, DUTY replaces itself with DITY. Subsequent reloads will then execute DUTY unless a disc initialization is called for, in which case the DIDY to DUTY, DITY to DUTY is repeated.

RESIDUAL COUNT:

A read for data from a terminal is for 245 characters. The actual number of characters transmitted is calculated from a residual count in the protected area of COMMON. Each partition's residual count address is kept at 0025 in that partition. Now examine TAG3 and instructions following in the MDT5 partition program. The contents of 0025 (P) (the residual count address for this partition) is moved to an instruction. The residual count (contents of the COMMON address moved in) is subtracted from 0245 in WORK3.

The residual count is actually 1 less than the number of characters remaining to be sent. Two of the characters sent are communications constants, not data. The actual character count sent is finally calculated by subtracting three from WORK3.

MDTS COMMUNICATIONS PROCEDURES

SECTION 10

MDTS System Communications Procedures*, Dial-In SCA

The procedures of the MDTS System SCA partition software which support Binary Synchronous Communications in a dial-in environment are described in the following sections:

- 1) ID Exchange (Handshake)
- 2) Function Text Analysis
- 3) Communications Standards
- 4) Transaction Transmission
- 5) Account Number Transmission
- 6) Special Features
- 7) Pictorial Examples

* Communications procedures described in this chapter adhere to conventions for Binary Synchronous Communications as outlined in document X3.3.4/212, Procedures for the Use of the Communications Control Characters of the American National Standard Code for Information Interchange in Specified Data Communications Links, of the American National Standards Committee X3 on Computers and Information Processing.

1) ID Exchange

A communications link between the MDTs System Ten and a "host" computer is accomplished by dialing and successfully transmitting six data characters of identification to the MDTs System Ten. The ID characters must contain a predetermined character configuration and be followed by an ENQ control character:

E
xxxxxxN
Q

The configuration for "xxxxxx" is determined at MDTs System generation time. Any ID transmission which does not match this configuration will cause a NAK response from the MDTs System Ten, the ERR19 message is generated (see MDTs System error message descriptions), and the MDTs System Ten will attempt to read a "host" computer ID again. If the ID received by the MDTs System Ten is valid, it will acknowledge acceptance by replying with its own six character identification followed by an ACKØ. The MDTs System Ten ID configuration is also specified at System generation time.

When this handshaking procedure has been successfully completed, the MDTs System Ten will continue communications with its Function Text Analysis phase. If a DLE,EOT is detected at any time during the handshaking, the MDTs System Ten will disconnect the line and force the "host" computer to redial to establish a communications link again.

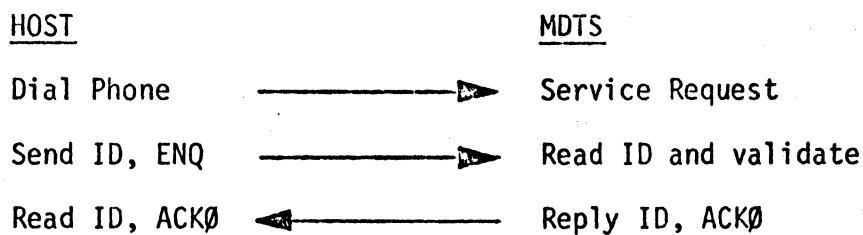

FIGURE 1. Normal ID exchange.

The MDTs System will reject any communications link for the following reasons:

- 1) Another communications function is active.
- 2) The MDTs System is inactive (see SYSDN and ENDAY commands).

2) Function Text Analysis

The transmission of a Function Text option by the "host" computer is the means by which it directs the MDTs System to perform the following functions:

| <u>Option</u> | <u>Description</u> |
|---|--|
| 000 | Transaction Transmission of the next single "logical day" or up to the most recent point-of-sale terminal transaction which has been logged on the disc when the next "logical day" is the "current day". See "*" below. |
| 0nn | Resend Transaction Transmission, where the "nn" is the two digit number of a specific MDTs System picture containing transactions for transmission. See "*" below. |
| 1 | Reset Transaction Transmission pointers. This Function Text is commonly used when the communications link is interrupted during "resend" or transaction transmission. If this has happened and the "host" computer does not wish to continue on from the point of previous interrupt, this Function Text option will reset ("erase") all traces of that interrupted function (see Transaction Transmission procedure). |
| 2 | MDTS System Status request. This causes the *STA message to be generated and transmitted to the "host" computer (see Special Features). |
| 5 | Account Number Transmission. |
| 6 | Clear account number file (see Special Features). |
| * When Function Text options 000 or 0nn are used immediately following reestablishment of a lost communications link, they will cause the MDTs System to resume the interrupted Function Text option if that Function Text option was a 000 or 0nn. Only the first character of new Function Text option is tested in this instance and any 'nn' characters will be ignored. (See also Function Text option 1.) | |

The Function Text option must be transmitted to the MDTs System Ten in the following format:

| | | | | |
|----|---|---|---|------|
| S | E | | | |
| T* | F | U | N | d..T |
| X | B | | | |

d...= One to three digits which correspond to a valid Function Text option.

The control characters DEL,EOT may also be transmitted by the "host" computer at this time to signal an orderly line disconnect (hangup). This will cause the MDTs System Ten to correspondingly relinquish its communications link.

Possible responses to receipt of a Function Text option from the "host" computer are:

ACK1 - This response means the MDTs System Ten has accepted the valid option and will now follow procedures necessary to service it.

NAK - A parity error was detected or too many characters were received. The "host" computer should resend the Function Text option.

WACK - The MDTs System Ten is busy servicing the previously received Function Text option. The only allowable "host" computer reply to this WACK is the standard ENQ or a terminating EOT.

EOT - This response by the MDTs System Ten means that the Function Text transmission received does not contain a valid configuration of characters. (See also Clear Account File description in Special Features section.) An ENQ reply from the "host" computer is expected in return and the MDTs System Ten will respond to that ENQ with an ACK0 and read for another Function Text option from the "host" computer.

HOST

MDTS

Send Function Text → Read Function Text

Read Reply ← Reply ACK1

FIGURE 2. Normal Function Text Transmission.

3) Communications Standards

The MDTs System SCA partition software adheres to standard binary synchronous communications procedures for the following situations:

Line Reversal (Turnaround)

This is the procedure by which one computer (Computer 'A' in Figure 3) ends its data transmissions and prepares to receive data from the other computer (Computer 'B' in Figure 3) without disconnecting the communications link. This is accomplished by 'Computer A' transmitting an EOT control character after sending its data block(s). The proper reply from 'Computer B' is an ENQ control character, which 'Computer A' acknowledges with an ACKØ.

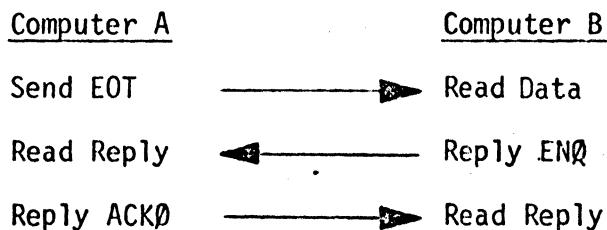

FIGURE 3. Normal Line Reversal.

As described above, the MDTs System Ten or the "host" computer may assume the role of 'Computer A'. This is determined by the operations which are required to service the Function Text option currently in effect in the MDTs System Ten computer.

All errors detected by the MDTs System during this sequence of operations are handled by the MDTs System SCA software Error Recovery procedures, as described in this section.

ACKn Sequences

The ACKØ and ACK1 sequences are used alternately in response to "host" computer transmissions requiring them. The MDTs System Ten will set the ACKn sequence to start at ACKØ upon establishing a communications link (see ID Exchange section) and Line Reversal.

Communications Fault (Timeout)

The MDTs System SCA partition software will retry all "read" type communications I/O instructions when a "fault" condition (no SYN characters received) is detected upon the first issuance of that instruction. (Refer to Singer System Ten publication 524-700721-M33, Synchronous Communications Adapter Reference Manual). The instruction will be re-executed up to 7 times before being reported by the ATT06 console message and disconnecting the line.

Error Recovery

The MDTs System SCA software will respond with a NAK to all transmissions of data which contain parity errors or are too large to be received in the circumstance. The MDTs System Ten will expect a retransmission of the correct data to be forthcoming.

The MDTs System SCA software will respond with an ENQ to all transmissions of control character responses from the "host" computer which contain parity errors or are invalid for the response expected (see Control Standards in this section).

Control Standards

The MDTs System SCA software adheres to the standard usages of the following control characters:

- WACK - This control character is used by the computer receiving data when it must temporarily stop receiving data transmissions. It is sent in place of an acknowledgment (ACKn) of the last complete data block received. The WACK implies a "wait before acknowledgment". The proper reply to a WACK is an ENQ control character however if the computer which is transmitting data does not wish to "wait", the EOT control character should be its reply. The EOT used at this time should cause the normal Function Text option termination sequence to be prematurely invoked (see Line Reversal in this section).
- EOT - This control character has the primary function of signifying the end of a sequence of data transmissions by a computer and signaling a change in its mode to receive data transmissions (see Line Reversal in this section). The MDTs System will also use the EOT control character for rejecting an invalid Function Text option (see Function Text Analysis section), and to force Line Reversal in an attempt to maintain its "slave" status with the "host" computer when a "receive data" sequence is ending (see Account Number Transmission section for example).
- ENQ - This control character is used primarily to "inquire" to another computer, what control character it had previously transmitted (see Error Recovery in this section). It is also used as a standard reply to the EOT and WACK control characters (see Line Reversal and WACK descriptions in this section).

DLE, EOT - This transmission is accepted by the MDTs System SCA software only when it is received in place of a Function Text option or during ID Exchange. If detected at any other time during a communications link, the MDTs System Ten will fault (time-out) on the next logical communications I/O instruction.

4) Transaction Transmission

Transmission of stored point-of-sale terminal transactions by the MDTS System SCA software is signified by directing the MDTS System Ten with the Function Text option number ØØØ or Ønn (see Function Text Analysis). Receipt of this Function Text option by the MDTS System Ten is expected to be followed by a Line Reversal from the "host" computer and allow the MDTS System Ten to assume a send data, read reply sequence.

Transaction data is transmitted in variable length transmissions of 18 to 250 data characters, framed with the control characters STX and ETB. More than one transaction may be contained in a single transmission, however, single transactions will not be split between two transmissions. The format is:

S Tddddddddd(upto 250 char.)T E
X B

The expected response to this transmission is the proper ACKn sequence from the "host" computer. If a NAK is received the MDTs System Ten will re-transmit the transaction block. The WACK or any invalid response received will cause the MDTs System Ten to send an ENQ and read for an ACKn reply again.

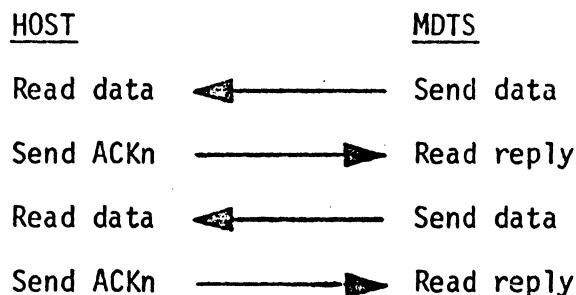

FIGURE 4. Normal Transaction Transmission.

The MDTs System Ten will terminate Transaction Transmission when the stored transaction data limits for the given Function Text option are reached (see Function Text Analysis section). This condition causes the MDTs System to relinquish its control of the communications line via Line Reversal (see Communications Standards section).

If the communications link is lost due to a fault detection (see Communications Standards), the MDTs System will retain all control information that enables Transaction Transmission to continue from its point of premature interrupt, i.e., the last transmission not

acknowledged, when the next Function Text option 000 or 0nn is received. To bypass this feature it will be necessary for the "host" computer to use Function Text option 1 prior to using Function Text option 000 or 0nn (see Function Text Analysis).

TTD Message.

During transmission of transactions to the "host" computer, it may become necessary to delay the transmission of a block of data because the MDTS System Ten has encountered one of the following conditions.

- a) A higher priority task is being serviced (i.e., reading point-of-sale terminals, etc.).
- b) The System is preparing to service the MDTS System SCA Function Text option.
- c) Disc errors are being encountered, and the MDTS System is attempting recovery.
- d) A required MDTS System Ten disc drive is disabled or inoperable.

The above conditions do not prevent SCA communications, however they do degrade the MDTS System's ability to service a Transaction Transmission Function Text option. While those conditions exist the MDTS System SCA will transmit a "temporary text delay" message (TTD) which has the following format:

| | |
|-------------------------|---|
| S | E |
| TTTTT...(18 letter T's) | T |
| X | B |

This message should be acknowledged and discarded by the "host" computer. However it is recommended that the "host" computer maintain a count of continuous TTD messages received and take some type of action when the count reaches an unreasonable limit.

*END Message.

When the end of a transaction picture (see Disc Organization section) in the stored point-of-sale terminal transaction file is encountered, an ATT01 console message displayed and an *END message is generated and placed in the Transaction Transmission data block. A transmission block containing this message may reside in the block alone or may be preceded by transaction data. It will never be followed by transaction data in

the same transmission block. The message format is:

S E
T(preceding data, if any)*ENDpppttttmncabbbbbbeeeeeet
X B

*END = Four characters to indicate the type of message.

pp = Two digits for this picture number. These two digits must be passed back to the MDTs program for a resend. A resend will be for a picture only. A resend can occur only by the passing of these two digits to the MDTs program. This picture number must be an even number, ranging from 02 to 98 inclusive.

tttttt = Six digits representing the number of transactions retrieved from the disc in this picture. This would correspond to the number of "P's" transmitted since each transaction begins with a "P".

m = A one digit flag with the following meaning:

1 = There are more pictures with data for this day on the disc. (This flag must be examined in connection with Field 5 to determine whether the data is in the current or a past day).

NOTE: See example 3 for exception.

0 = There are no more pictures in this day with data. The next MDTs write will be an EOT character.

n = A one digit flag with the following meaning:

1 = Next day to be sent will be the current day. The next MDTs write will be the EOT Line Reversal procedure. The host may pick up this data in the current day by sending a normal poll function following the line reversal procedure. It may leave the data for a subsequent poll by changing functions or by signaling a disconnect.

0 = The next day to be sent is not the beginning of the current day.

- c = A one digit flag with the following meaning:
 1 = This picture is in the current day.
 0 = This picture is not in the current day.
- a = A one digit flag indicating terminal activity with the following meaning:
 1 = All terminals are currently closed.
 0 = At least one terminal is not closed.
- bbbbbb = Six digit disc address of beginning transaction file sector for the picture in Field 2.
- eeeeee = Six digit disc address of ending transaction file sector for the picture in Field 2.

*END EXAMPLES

Field 4, 5, and 6 may be used by the host to determine its next logical step.

The following examples illustrate some of the combinations of Fields 4, 5, and 6.

Example 1: No data has been transmitted for three days. Today is Thursday; the store is open and running into one picture. The other days are configured as follows:

| <u>Day</u> | <u>Picture Code</u> | <u>4</u> | <u>5</u> | <u>6</u> | <u>Next MDTS Write</u> |
|------------|---------------------|----------|----------|----------|---|
| Monday | 04 | 0 | 0 | 0 | EOT character & line reversal sequence. |
| Tuesday | 06 | 1 | 0 | 0 | Next data block. |
| | 08 | 1 | 0 | 0 | Next data block. |
| | 10 | 0 | 0 | 0 | EOT character & line reversal sequence |
| Wednesday | 12 | 1 | 0 | 0 | Next data block. |
| | 14 | 1 | 1 | 0 | EOT character & line reversal sequence. |
| Thursday | 16 | | | | |

This example illustrates three consecutive polls (function code 000) to pick up Monday's, Tuesday's, and Wednesday's data. If a fourth poll were sent by the 360 after receiving the third EOT character from the MDTs, the data in picture 16 will be transmitted and Thursday will be reconfigured as follows:

Example 2:

| <u>Day</u> | <u>Picture Code</u> | <u>4</u> | <u>5</u> | <u>6</u> | <u>Next MDTs Write</u> |
|------------|---------------------|----------|----------|----------|------------------------|
| Thursday | 16 | 0 | 0 | 1 | EOT character |
| | 18 | | | | |

Example 3: If data came into the system during the transmission of picture 16 of Thursday's data, the flags will be 1 0 1, indicating more data to come in this day. Picture 18 will be closed, picture 20 opened, and the data in 18 transmitted. This process will occur only this once, however. If data came into picture 20 during the transmission of 18, the *END message will reflect this with 1 0 1, but an EOT character and line reversal sequence will be transmitted next.

5) Account Number Transmission

Transmission of account numbers to the MDTs System Ten from the "host" computer is signified by directing the MDTs System Ten with the Function Text option number 5 (see Function Text Analysis). This causes the MDTs System Ten SCA partition to commence reading and acknowledging successful transmissions of up to 250 characters of data framed with the control characters STX and ETB (or ETX). The acceptable format of each account number transmission block is:

| | | |
|--|---|---|
| S | E | E |
| Tnnnnn...na(nnnnn...nannnn...na[up to 250 char])T (or T) | | |
| X | B | X |

nnnnn...n = Each account number, plus display code. This must be equal in length to the maximum account number size specified during MDTs System Initialization.

a = Action code, used to determine what is to be done with the associated account number:

2 = Add the number.

3 = Delete the number.

4 = Change the display code specification.

5 = Add the number.

Normal response to the "host" computer for an accepted block of transmitted data is the proper ACKn sequence.

The NAK response by the MDTs System Ten signifies that the last transmission block received was in error for one of the following reasons:

- 1) A parity error was detected.
- 2) The combined count of control and data characters received exceeds 252.

When the NAK response is transmitted, the MDTs System Ten will accept a resend of the transmission block in error or an EOT to terminate the Function Text option.

In the event that the MDTs System Ten becomes temporarily preoccupied with other services (i.e., point-of-sale terminal servicing, etc.) a WACK response is transmitted to the "host" computer which signifies that the last block of data is accepted but the proper ACK response will be delayed until the MDTs System Ten is again free to accept the next transmission block. The only replies from the "host" computer that the MDTs System Ten will accept in response to a WACK is the standard ENQ reply or the EOT reply which will terminate the Function Text option.

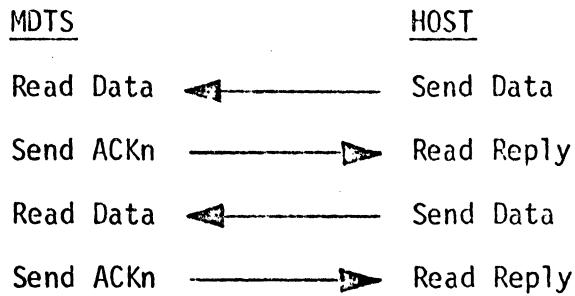

FIGURE 5. Normal Account Number Transmission.

Termination of Account Number Transmission is accomplished when the MDTs System receives an EOT control character instead of data. This will cause the MDTs System to reply ENQ and then force itself into a "slave" status to the "host" computer by responding EOT to the ACKn from the "host".

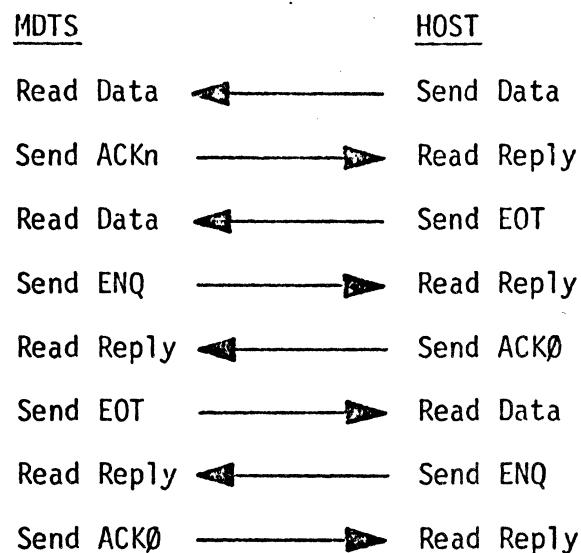

FIGURE 6. "Slave" Status Assumed By MDTs System.

It will be noted that the procedure shown in Figure 6 is two consecutive Line Reversal sequences where the "host" is 'Computer A' and then the MDTs System is 'Computer A' (see Line Reversal in Communications Standards section). Following this sequence the MDTs System will resume Function Text Analysis.

6) Special Features

The MDTs System SCA software package includes the following features which supports conversational "host" computer control of MDTs System functions:

MDTS System Status Request

This feature allows the "host" computer to interrogate the MDTs System Ten operational status. This is accomplished by the Function Text option 2 which, when received by the MDTs System Ten, requires a Line Reversal by the "host" computer to allow the MDTs System Ten to transmit a *STA message. When that message is successfully acknowledged by the "host" computer, the MDTs System Ten will commence Line Reversal and then resume Function Text Analysis.

The *STA message is in the following format:

| | |
|--------------------------------|---|
| S | E |
| T*STAcapnnnnnnxxyybbbbbeeeeeet | |
| X | B |

*STA = Four characters identifying the message.

c = One digit indicating the status of days in the MDTs System. Its values are:

1 = The next day to transmit is the current day.

0 = The next day to transmit is not the current day.

NOTE: Two interesting situations may not be readily apparent. The end of a day is determined by an operator command. First, should the operator have failed to enter this command, this flag will be a 1. The data is still available by polling in a normal way. Second, had the operator erroneously generated a series of days without data, this flag will be 0 even though the day which is now receiving data may not have ended.

a = A one digit flag indicating terminal activity with the following meaning:

1 = All terminals are currently closed.

0 = At least one terminal is not closed.

p = Results of the previous communications link. The values are:

Space = Terminated properly.

Digit = Value indicating the last communication option that terminated incorrectly. This corresponds to the function code digit such as 0 for poll, etc.

t = Previous poll type.

0 = The previous poll was properly terminated.

R = The last poll was a resend abnormally terminated.

D = The last poll was a data poll abnormally terminated.

NOTE: The system is specifically designed to pick up the prematurely ended poll. If the user does not wish to pick up at the dropped point, he must signal a system reset before specifying a different function.

nnnnnn = Six digits indicating the number of account numbers currently on the credit file.

xxyy = Four digits used to indicate the number of logical days remaining to be sent to the host computer. The format is "xxyy" where "xx" indicates next logical day to be sent and "yy" indicates the current logical day.

bbbbbb = Six digit address of the beginning sector of stored transaction data in the MDTS System.

eeeeee = Six digit disc address of the ending sector (exclusive) of stored transaction data in the MDTS System.

Reset Transaction Transmission Pointers

This feature permits the "host" computer to reset to a "clear" state, the Transaction Transmission buffers and pointers after loss of communications link for a previous Transaction Transmission Function Text option. The transmission pointers for the stored transaction file in the MDTS System are reset for the beginning of the MDTS System picture which was partially transmitted prior to the communications loss.

This feature is invoked by Function Text option 1. The MDTS System Ten will expect an EOT transmission after it acknowledges this Function Text option. Upon receipt of the EOT, the MDTS System Ten will commence Line Reversal and then resume Function Text Analysis.

Clear Account File

This feature allows the "host" computer to "prepare" the MDTs System storage area that was assigned to the Negative Credit File during MDTs System Initialization. This preparation consists of removal of all account numbers from the file.

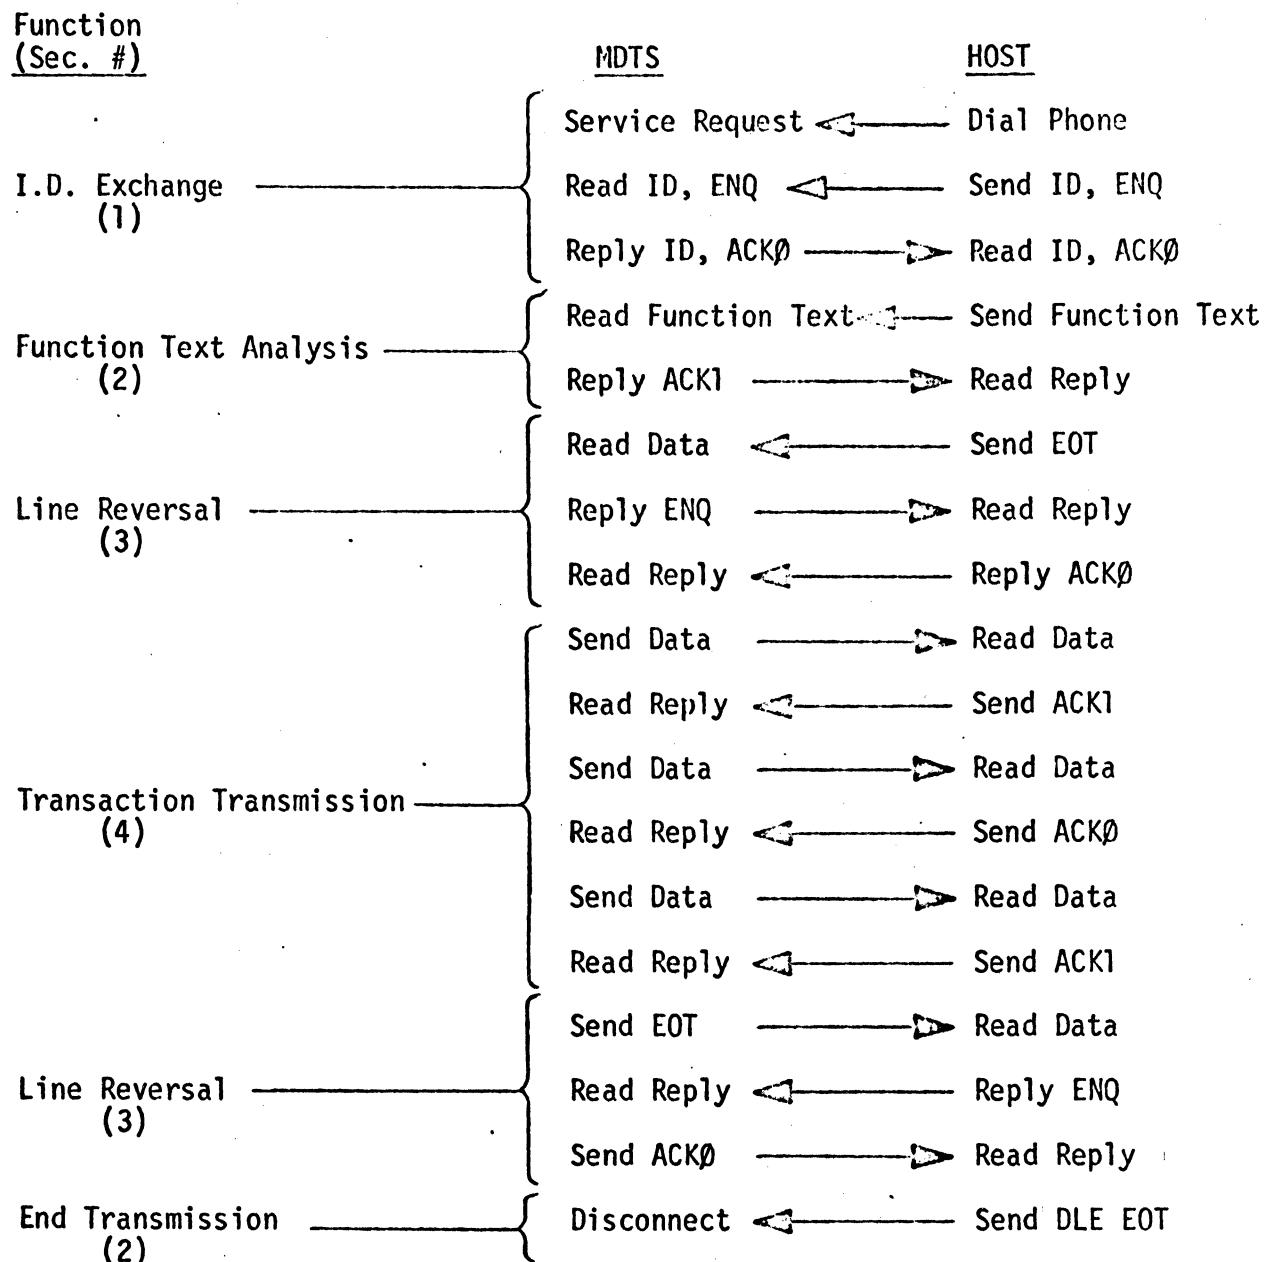

This feature is invoked by Function Text option 6. The MDTs System Ten will expect an EOT transmission after it acknowledges this Function Text option. Upon receipt of the EOT, the MDTs System Ten will commence Line Reversal and then resume Function Text Analysis.

NOTE: During execution of the Function Text option 6, no other Function Text options will be accepted (see WACK description in Function Text Analysis section).

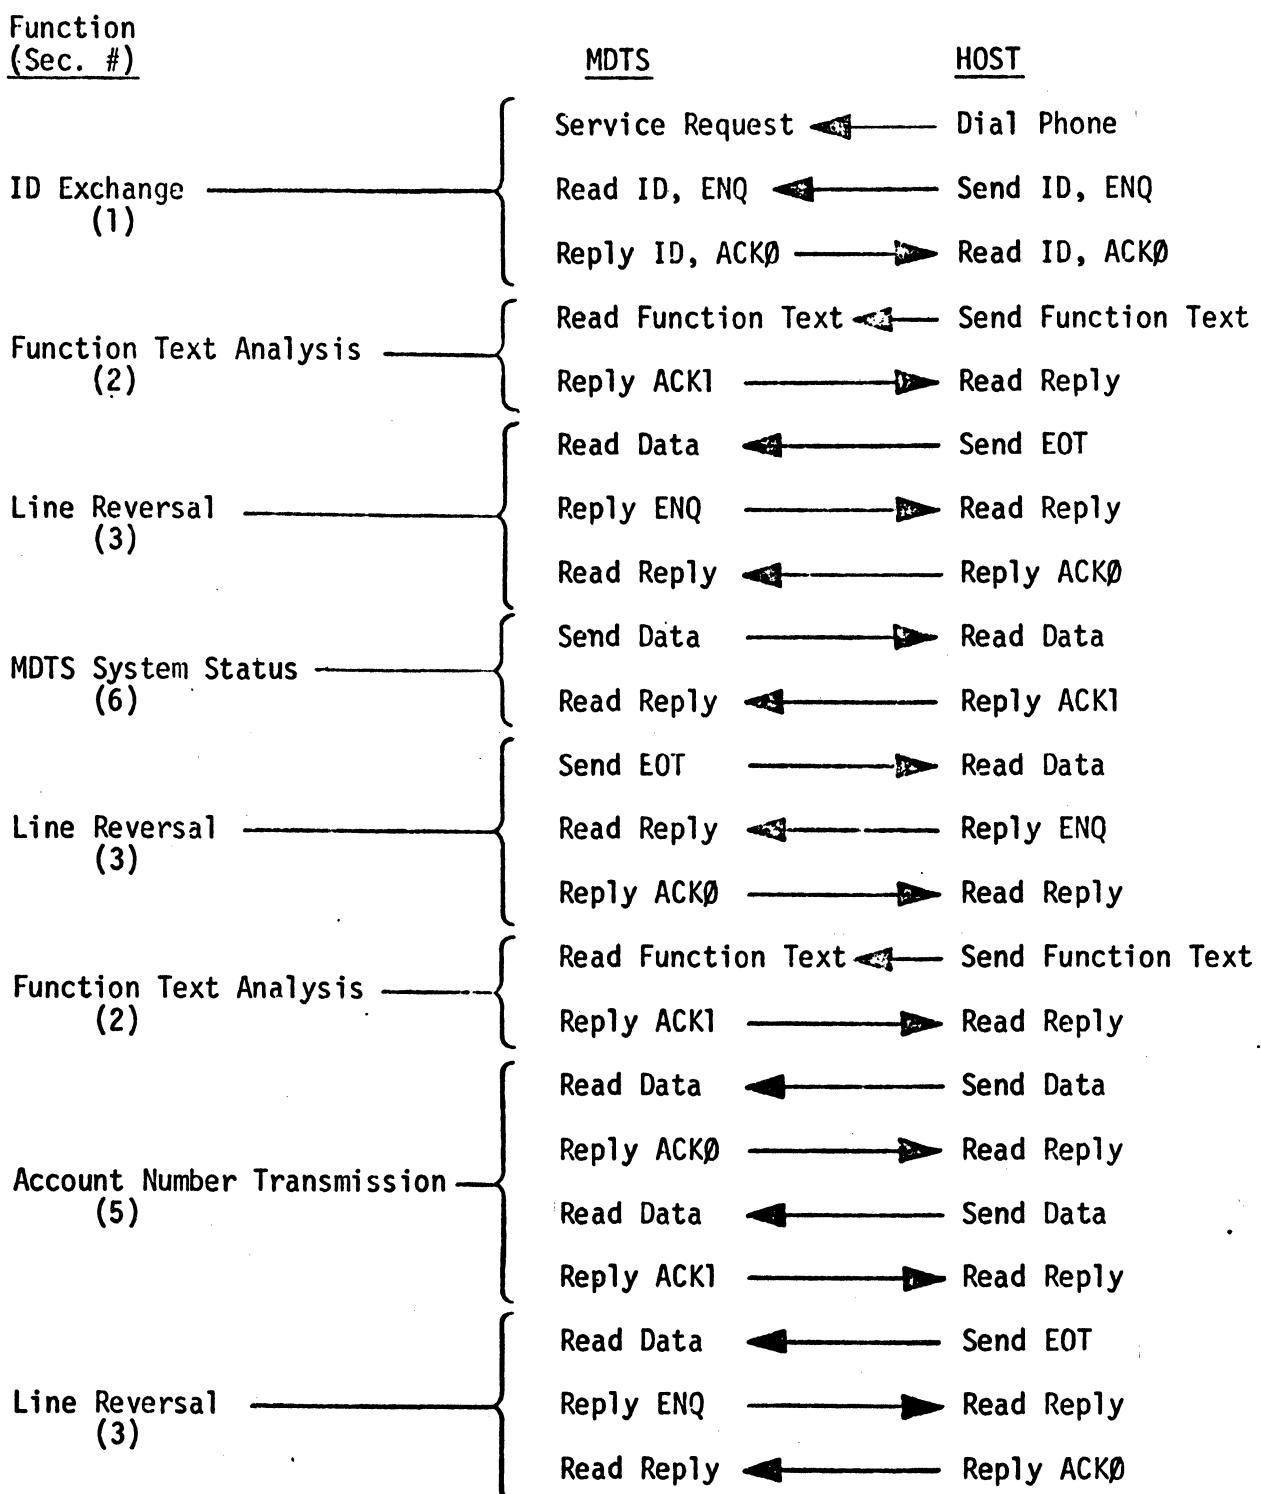

7) Pictoral Examples of MDTs System Communications.

The following examples attempt to show the normal communications I/O sequences between a MDTs System Ten and another computer designated as "HOST".

Example 1. Transaction Transmission.

Example 2. MDTs System Status Request Followed By Account Number Transmission.

CONSOLE CREDIT FILE UPDATE

Section 11

7-13-71

CR-0602

CONSOLE CREDIT FILE UPDATE

General Description

The facilities of Console Credit File Updating, as described in this section is considered an optional feature of the MDTs "Collective Store and Forward System with Credit Authorization". The routine uses as its load vehicle the RBSA program NFR200.

Capabilities have been provided for the adding of credit numbers, deleting numbers, and/or changing them. The routines may also be used to alter the display code of any number.

The security of the credit file rests solely with the operator and his ability to use this option. Audit trails and proofs other than the console typewriter sheet have not been provided.

General Operating Features

The Credit File Update routine may be accessed from either the Workstation or the Console Monitor¹. It should be kept in mind, that all updating of the file is handled through normal MDTs System routines. All message reporting (errors, warnings, etc.) are handled by the Console Monitor regardless of the device used. The routine is entered by securing a Service Request, keying the update's mnemonic to call the routine into operation, and entering a phase identifier to denote the operation intended.

Phases applicable to the routine are; ADD (to add numbers to the file), DELETE (to remove existing numbers from the file), or CHANGE (to alter the display code of an existing number). Upon the completion of entering any phase's account numbers, the routine may be terminated by signaling for the end-of-job, or another phase may be used by signaling for an end-of-phase.

Normal MDTs message processing will occur on-line with the Credit File Update and will be reported by the Console Monitor. While this routine is in operation, all Service Requests from the Workstation or Console Monitor will be ignored.

- *1. The Workstation is the Model 70 Workstation assigned Device Address 7.
- *2. The Console Monitor is the Model 70 Workstation or Model 7102 assigned Device Address 0.

Due to the address modifications required to allow interfacing with existing MUDS and RBSA coding techniques, it is imperative that any update be terminated only by signalling an end-of-job. If the routine is interrupted by a LOAD condition on the Console Monitor, a restart branch code of "P0PP050300" must be initiated and the end-of-job code entered properly. If this procedure is not adhered to, the system will remain in the Console Credit File Update routine indefinitely.

Operator Instructions

1. Secure a "Service Request" on the Workstation or Console Monitor. The device used in obtaining the Service Request will be used in entering the account numbers, and in communicating with the Credit File Update routine.
2. When the Service Request is honored, enter the routine mnemonic, "NAFUD", the system will respond in one of the following possible manners.
 - a. If the system is not in a "SYSUP" state, a message will be printed on the Console Monitor "SYSTEM NOT IN SYSUP CONDITION" to indicate this condition, and normal MUDS cycling will continue. (See SYSUP, SYSDN and ENDAY commands in Section 5, "Workstation Commands").
 - b. If the system is currently involved in communications routines, a message will be printed on the Console Monitor, "COMMUNICATIONS IN PROGRESS", to indicate this condition and normal MUDS cycling will continue. Console Credit File Updating may not occur simultaneously with communications procedures due to conflicts in buffer uses.
 - c. If the system is in a "SYSUP" state and communications are not in progress, it is therefore accessible and will respond with a message on the Console Monitor, "START CREDIT FILE UPDATE INTERFACE - ENTER PHASE", to indicate that the system will accept Credit File Updating.
3. When the system is operable and has responded with "START CREDIT FILE UPDATE INTERFACE - ENTER PHASE", the operator must respond with a phase name as described below followed by a "unit separator³".

*3 The "Unit Separator" is used in completing all responses to messages generated by this routine and must follow each response or account number entered. The unit separator is generated on the Workstation by depressing the ENTER Key, whereas on the Model 7102 it requires the depressing of the Control and / Keys simultaneously.

- a. ADD = to add account numbers to the Credit File.
- b. DELETE = to remove existing account numbers from the Credit File.
- c. CHANGE = to alter the display code of an existing account number.
- d. EOJ = to halt processing and return to normal MDTs processing.

An error in entering the Phase name, an account number or an end request, is bypassed by pressing the ERROR Keys⁴. The message "INVALID ENTRY. RE-ENTER" is printed on the Console Monitor and the system waits for the proper data to be entered.

- 4. Having entered one of the phase names described in 3 above, the operator may then enter as many 13 digit account numbers as are applicable to the phase. The check digit is included in the account number and must be entered. All account numbers must be followed by the display code. The total entry per account must be 14 characters. Account numbers with less than 13 digits must be preceded with as many zeros as are required to make a 13 digit number. All digit entries must be followed by a "Unit Separator" (See footnote 3, pg. 11-2).
- 5. Should the system be unable to dispose of an account number entered as a "DELETE" or "CHANGE", the number is typed on the console monitor. (See WRNØ3 and WRNØ4 pg. 11-4). In as much as the "Check Digit" is required for number entry only, the "Display Code" replaces the Check Digit on the Credit File. Any account number accompanying the WRNØ3 and WRNØ4 will reflect this replacement of the Check Digit by the Display Code.
- 6. At the conclusion of any of the phases described above, the operator may then enter one of the following:
 - a. EOP = indicates the end of the phase. The message "END OF PHASE" is printed on the Console Monitor and the System waits for the next phase name to be entered as discussed in 3 above.
 - b. EOJ = indicates the end of the Console Credit File Update activity and returns the system to normal MDTs cycling. The message "END CREDIT FILE UPDATE FROM CONSOLE" is printed on the Console Monitor.

*4 Errors in entering data may be bypassed on the Workstation by pressing the ERROR Key, whereas on the Model 71Ø2 the combination of Control-A, Control / is required.

Possible messages printed on the Console Monitor in conjunction with the Console Credit File Update.

| Message | D E V | Caused By | Required Action |
|---|-------------|---|--|
| ATT03 | B | Entering EOJ to exit from the routine. | None. |
| COMMUNICATIONS IN PROGRESS | A | The system is involved in communications routines. Credit File Updating cannot be performed due to a conflict in buffer area. | None - Communications must be completed. |
| END CREDIT FILE UPDATE FROM CONSOLE | A | Entering EOJ to exit from the routine. | None. |
| END OF PHASE | A | Entering EOP to change from one phase to another | Enter a phase name to continue File updating. |
| ERR02 | B | Account number length incorrect. | Re-enter the proper account number as described in Number 4 of the "Operator Instructions". |
| INVALID ENTRY. RE-ENTER | A | Entering an incorrect Phase name, account number, or end request and pressing the ERROR key. | Enter proper name or number to continue. |
| START CREDIT FILE INTERFACE - ENTER PHASE | A | Service Request honoring of Routine Nemonic "NAFUD". | Enter "ADD", "DELETE" or "CHANGE", to process, or "EOJ" to abort the routine. |
| SYSTEM NOT IN SYSUP CONDITION | A | The MDTs system is not operational at the time the service request is honored. (See SYSUP, SYSDN and ENDAY commands in Section 5) | Complete operations involved in and follow directions required in making the system operational. |
| WRN03 aaaaaaaaaaaad | B | Attempt to Delete a non-existant account aaaaaaaaaaaa = the first 12 digits of the number entered d = the Display Code which has replaced the Check Digit. | Enter proper account number, including check digit and display code. |
| WRN04 aaaaaaaaaaaad | B | Attempt to alter the Display Code of a non-existant account. aaaaaaaaaaaa = the first 12 digits of the number entered. d = the Display Code which has replaced the Check Digit. | Enter proper account number, including check digit and display code. |
| WRN05 | B | Credit File area Full for numbers which would randomize to that area. Does not imply all Credit File Area is full. | None. Account number is printed but not written to the credit file. |

 A = Device at which the Service Request was secured to initiate the routine.

B = Console Monitor, Device 0 only.

IMAGE

FALL THROUGH FIRST TIME
INITIALIZE RESULTANT ADDRESS
SET SWITCH FOR ADDIT TRANS
TEST FOR EMPTY COMMON BUFFER
IF IT IS EMPTY EXIT FROM ROUTINE

ADDRESS OF COMMON BUFFER AREA
SET COMMON BUFFER DATA LENGTH
ADD MBUFF SIZE TO CURRENT COMMON
TEST FOR TOTAL EXCEEDING 250 CHAR
FULL IF PAST 250
IR2 IS USED AS A SOURCE PTR
SET COMMON DATA LENGTH IN THE FLAG
IS MBUFF MESSAGE LESS THAN 100 CHR
GO TO 100 CHRS MOVE
FIRST DIGIT OF MOVE LENGTH
2ND DIGIT
TRANSFER INSTRUCTION

MUST FOLLOW LABEL MARK
ADJUST THE COMMON BUFFER POINTER
GO TO MARK MBUFF EMPTY
USE ANY UNUSED SPACE
WORK AREA FOR COMMON BUFFER SIZE
SET TRANSFER LENGTH
BAZ IS A DUMMY LABEL
INCREMENT INPUT POINTER
ADJUST THE COMMON BUFFER POINTER
REDUCE MBUFF MESSAGE LENGTH
TRY TEST ON MESSAGE LENGTH
USE ANY UNUSED SPACE
HOLD AREA FOR NEXT DAY AND PICTURE
CLEAR MBUFF FILL FLAG
IS THIS LAST MESSAGE
RELEASE PARTITION IF IT IS NOT
IS *END FOR A RESEND FUNCTION ?
SKIP *END MSG TEST IF IT IS
TEST *END MESSAGE FOR MORE TO COME
YES, GO TO MAR2

CLEAR THE MORE TO COME FLAG
SAVE PSFLAG AND CLEAR IT
SET LSTREC FLAG ON
SET COMMON BUFFER FLAG FOR 'FULL'
RESET BRANCH TO 1ST TIME
RETURN

TRANSMISSION TO HOST COMPLFTE
IS THERE ANY DATA CURRENT
SKIP NEXT INSTR IF NO DATA
FLAG DATA IS COMING
SAVE THE NEXT DAY'S NUMBER
RESET THE MOR2CM FLAG
GO UPDATE THE SYSSS
